

# GRUAN OZONESONDE TECHNICAL DOCUMENT

Version 1.1.0.3

## Purpose of this Guide

This Document to GCOS Reference Upper Air Network (GRUAN) ozonesonde operations provides both mandatory operating protocols and non-mandatory recommendations for measurements of vertical ozone profiles using ozonesondes within GRUAN. This Document relies on the standard operating protocols, instrument selection, and uncertainty estimates and calculations from the the WMO/GAW Report #201 [Smit et al., 2014], Assessment of Standard Operating Procedures for Ozone Sondes (ASOPOS) panel recommendations, and the large body of peer-reviewed literature on ozonesondes. This Document also builds on the GRUAN *Manual* and *Guide to Operations* (herein referred to as GCOS-171). As in the GRUAN Manual and Guide, mandatory operating protocols are distinguished by the words ‘shall’ or ‘must’ while guidelines are distinguished by the words ‘could’ or ‘should’.

The primary goal of GRUAN is to provide vertical profiles of reference measurements suitable for reliably detecting changes in global and regional climate on decadal time scales. GRUAN’s goals have been agreed to by GCOS (Global Climate Observing System) and WMO (World Meteorological Organization). Ozone is classified as a priority 2 essential climate variable (ECV) within GRUAN. GRUAN ozonesonde measurements will provide a calibrated reference standard for global satellite-based measurements of atmospheric ozone. GRUAN ozonesonde measurements will also ensure that potential gaps in satellite measurement programmes do not invalidate the long-term ozone record, and will provide data to fully characterize the properties of the atmospheric column. Because ozone is a key radiatively active gas, vertically resolved measurements of the ozone profile are essential for characterizing radiative transfer through the atmosphere column.

From Section 6.1 of GCOS-171

“GRUAN will not prescribe the use of specific instruments in the network since the emphasis is not on prescribing an instrument, but rather on prescribing the capabilities required of an instrument and allowing individual sites to select an instrument that achieves those capabilities.”

This GRUAN Ozonesonde Technical Document includes frequent references to the requirements described in the GRUAN *Guide to Operations* (GCOS-171), and provides additional ozonesonde-specific requirements not described in GCOS-171. It defines the requirements on random and systematic uncertainty and long-term stability for the operations of all ozonesonde instruments in use at GRUAN sites. This Document establishes the philosophy under which GRUAN ozonesondes shall operate and inform current and future GRUAN sites of the expected *modus operandi* for ozonesonde operations at GRUAN sites. The overall framework under which an ozonesonde will operate in GRUAN is hereafter referred to as the ‘GRUAN Ozonesonde Programme’.

43 The GRUAN community is not the international authority on ozonesonde operations. This  
44 Document has been developed in close collaboration with international leaders in the  
45 development of ozonesonde standard operating procedures (SOPs). These are the principals in  
46 the WMO ozonesonde community (Dr. H. Smit/Research Centre Jülich GmbH, and collaborators  
47 who developed ASOPOS), the Network for Detection of Atmospheric Composition Change  
48 (NDACC) working group, and the principals in the Southern Hemisphere ADDitional  
49 OZonesondes (SHADOZ) network.

50 Relevant information from this GRUAN Ozonesonde Technical Document is expected to be  
51 incorporated into the WMO Manual on the Global Observing System (WMO-No. 544) and the  
52 Guide on the Global Observing System (WMO-No. 488). This Guide may be additionally  
53 supported by a series of technical documents listed on the GRUAN web site at  
54 <http://www.gruan.org>.

# 146 1 INTRODUCTION

## 147 1.1. Ozonesonde heritage

148 Ozone is a key trace gas in Earth's atmosphere. In the stratosphere it absorbs incoming solar  
149 radiation in the UVC (<280 nm) and UVB (280-320 nm) portions of the spectrum. Because  
150 radiation at these wavelengths has sufficiently high energy to be detrimental to biological  
151 systems, the stratospheric ozone layer provides an essential screen thus protect life on Earth's  
152 surface. During the latter half of the 20<sup>th</sup> century the stratospheric ozone layer was depleted, most  
153 severely over Antarctica, as a result of anthropogenic emissions of ozone depleting substances.  
154 As a result of the successful implementation of the Vienna Convention for the Protection of the  
155 Ozone Layer and its Montreal Protocol (including amendments and adjustments to the Protocol),  
156 emissions of ozone depleting substances have declined dramatically and the status of the ozone  
157 layer is expected to return to a mid-20<sup>th</sup> century state in the second half of the 21<sup>st</sup> century.

158

159 The effects of ozone are not always positive. Ozone is a key component of photochemical smog  
160 and high levels of ozone are associated with poor air quality. The common saying is that ozone is  
161 'nice from far but far from nice'. Ozone in the troposphere also acts as a strong oxidizer and this  
162 removes many compounds, including toxic substances, from the air. Ozone levels therefore play  
163 a role in determining the tropospheric lifetimes of many compounds. Ozone is also a greenhouse  
164 gas, absorbing outgoing infrared radiation from Earth's atmosphere. Because of its importance  
165 both as an absorber of incoming solar UV radiation, and as an absorber of outgoing infrared  
166 radiation, it is essential that changes in ozone concentrations throughout the atmosphere are  
167 carefully monitored.

168

169 The vertical distribution of ozone in the atmosphere can be monitored using a range of different  
170 techniques including satellite-based (solar occultation, limb-sounding, nadir viewing)  
171 instruments, balloon-borne *in situ* instruments (ozonesondes, dropsondes), and ground-based  
172 remote sensing systems (lidars and microwave radiometers). Ozonesondes fulfil an important  
173 role in this suite of techniques by providing very high vertical resolution ozone profiles from the  
174 surface to the middle stratosphere with small measurement uncertainties, capable of making  
175 measurements during periods of no sunlight, and can be easily deployed from remote locations  
176 such as ships or small islands.

177

178 A number of quasi-independent ozonesonde measurement programmes have been established  
179 globally to monitor changes in the vertical distribution of ozone. The WMO/GAW<sup>1</sup>, SHADOZ  
180 and NDACC communities have established an expert panel, ASOPOS (Assessment of Standard  
181 Operating Procedures for Ozonesondes), to develop standard operating procedures for  
182 ozonesonde measurement programmes. This Document builds considerably on the large body of  
183 material already developed by ASOPOS [Smit et al., 2012].

184

---

1

A complete list of all acronyms appearing in this Document is provided at the end of the document.

185 Because long-term satellite-based measurements of ozone in the troposphere and UTLS are not  
186 currently available, the ozonesonde record provides the primary source for deriving ozone trends  
187 in the troposphere and UTLS, especially in the climate sensitive region around the tropopause.  
188 When combined with satellite-based measurements of ozone, they can provide a global, multi-  
189 decadal data set extending from the surface to the mesosphere for long-term ozone trend  
190 detection (Bodeker et al., 2012).

191

192 There are challenges in making ozonesonde measurements such that will meet the needs of  
193 GRUAN users (see Section 1.2). While instruments may be well calibrated, because instruments  
194 are seldom recovered after flight, each well calibrated instrument is discarded after each profile  
195 measurement. Ensuring inter-instrument calibration in an environment where instruments from  
196 different manufacturing batches may show systematic biases, presents a challenge.

## 197 1.2. **The purpose of ozonesondes within GRUAN**

198 As detailed in GCOS-112, GRUAN's objectives are to:

- 199 i) Provide long-term high quality climate records;
- 200 ii) Constrain and calibrate data from more spatially-comprehensive global observing systems  
201 (including satellites and current radiosonde networks); and
- 202 iii) Fully characterize the properties of the atmospheric column.

203 To achieve these goals with respect to ozone, sites within the network should provide vertical  
204 profiles of reference measurements of ozone for reliably detecting changes in global and regional  
205 climate, on multi-decadal time scales, for major climatically distinct regions of the globe.  
206 Changes in ozone, both in the stratosphere and troposphere are known to drive changes in global  
207 and regional climate. Reference within GRUAN means that, at a minimum, the observations are  
208 tied to a traceable standard, that the uncertainty on the measurement has been determined, and  
209 that the entire measurement procedure and set of processing algorithms are properly documented  
210 and accessible (Immler et al., 2010). Within this framework, ozonesonde measurements are  
211 classified as ancillary measurements.

212

213 Potential uses of such ancillary measurements include:

214

- 215 i) Providing measurements at GRUAN sites that complement the priority 1 measurements of  
216 temperature, pressure and water vapour and priority 2 measurements of ozone.  
217 Understanding changes in the vertical distribution of ozone is required to understand  
218 changes in the vertical distribution of temperature.
- 219 ii) Providing redundant measurements of the ozone profile.

220 The four key user groups of GRUAN ozonesonde ozone profiles are the same as those identified  
221 in the GRUAN *Guide to Operations*, viz.:

- 222 i) The climate detection and attribution community. Understanding changes in the vertical  
223 distribution of ozone is essential to understanding changes in the thermal structure of the  
224 atmospheric column.

- 225 ii) The satellite community. Validating satellite-based measurements of ozone is recognized as  
226 an essential requirement of the GRUAN ozonesonde programme.
- 227 iii) The atmospheric process studies community. High vertical resolution measurements of the  
228 ozone profile, with well resolved measurement uncertainties, provide key data for  
229 understanding atmospheric processes. Many aspects of stratospheric dynamics and the  
230 dynamics associated with stratosphere-troposphere exchange can be studied using ozone  
231 profiles from ozonesondes. Ozonesonde measurements have played a key role in  
232 determining ozone loss rates in the Arctic vortex (Rex et al., 1998).
- 233 iv) The numerical weather prediction (NWP) community.

### 234 **1.3. Organization and design of the GRUAN Ozonesonde Programme**

235 GRUAN operates under the joint governance of GCOS and WMO as a WIGOS Implementation  
236 Project. A defining attribute of GRUAN is the standardisation and centralization of data  
237 processing with the goal of ensuring network-wide homogeneity of the resultant data products.

#### 238 **1.3.1. Terminology**

239 *A GRUAN Ozonesonde Programme* is an ozonesonde measurement programme implemented at  
240 a site and having been assessed and certified as defined in Sections 3.1 and 3.2.

241 *A GRUAN Ozonesonde instrument* is one of the instruments employed in a GRUAN ozonesonde  
242 programme. These are balloon-borne electrochemical concentration cell (ECC) ozone sensors  
243 measure high vertical profiles of ozone, pressure, temperature, and relative humidity. ECC ozone  
244 sensors are described in Section 2.1

245 *A GRUAN Ozonesonde Product* is an ozone product resulting from the measurements made  
246 within a GRUAN ozonesonde programme. A GRUAN Ozonesonde Product is always produced  
247 by the GRUAN Ozonesonde Analysis Software System (GOASS, see Section 3.7) designed to  
248 implement the requirements and recommendations defined in this document.

#### 249 **1.3.2. Responsibilities**

250 The GRUAN Task Team on Sondes (TTS), in consultation with the GRUAN Lead Centre and  
251 Task Team on Ancillary Measurements, is responsible for integrating best ozonesonde  
252 measurement practices into GRUAN operations. These best practices shall be synthesized in the  
253 form of requirements and recommendations compiled in this Document and shall be  
254 implemented in all certified GRUAN Ozonesonde Programmes.

255 GRUAN sites hosting a GRUAN Ozonesonde Programme shall use a designated system of  
256 methods, techniques and facilities in full compliance with the requirements and  
257 recommendations detailed in this document. For any given GRUAN Ozonesonde Programme,  
258 this system will not be changed without advanced notice to the TTS and GRUAN Lead Centre.  
259 GRUAN Ozonesonde Programmes incorporate a programme to validate the stability and  
260 uncertainty of the measurements, agreed with WG-GRUAN, and managed in detail by the  
261 GRUAN TTS and GRUAN Lead Centre. This assurance programme comprises three mandatory  
262 components, which are the *GRUAN Standard Operating Procedures* (SOPs) for all GRUAN  
263 ozonesonde instrument calibration (described in Section 3.5), the RSLaunchClient (described in  
264 Section 3.6), and the GOASS (described in Section 3.7).

265 The design of GRUAN Ozonesonde Programmes shall recognise the heterogeneity of the  
266 network of sites, many of which will have primary responsibility to networks other than  
267 GRUAN. GRUAN Ozonesonde Programmes shall integrate, where possible and when feasible,  
268 with other international long-term monitoring programmes.

269 GRUAN Ozonesonde Programmes shall be responsive to the latest technological and scientific  
270 progress in ozonesonde measurement techniques and observational requirements. Non-GRUAN  
271 ozonesonde development work can continue at a GRUAN site in collaboration with the TTS  
272 until mature and validated, at which point any improvements can be introduced into GRUAN  
273 operations with the agreement of the TTS and GRUAN Lead Centre.

274 WG-GRUAN, the GRUAN Lead Centre and TTS will act as the interfaces between GRUAN and  
275 the community of users of GRUAN ozonesonde products.

#### 276 **1.4. Implementation of GRUAN Ozonesonde Programmes**

277 The implementation of the GRUAN Ozonesonde Programmes, as a whole, and specific issues  
278 relevant to an individual Ozonesonde Programme shall be guided by the TTS and WG-GRUAN.  
279 These two teams will work with other relevant expertise in support of GRUAN and coordinate  
280 with the GRUAN Lead Centre.

281 A GRUAN Analysis Team for Network Design and Operations Research (GATNDOR) shall  
282 undertake focused, short-term research to address specific topics identified by the WG-GRUAN.  
283 The work will be conducted in coordination with the TTS and with other GCOS programmes  
284 when appropriate.

285 The WG-GRUAN and TTS shall use this report which establishes standard operational  
286 procedures (SOPs) and metadata requirements for all GRUAN Ozonesonde Programmes. The  
287 TTS shall evaluate the appropriateness of uncertainty estimates, the usefulness of particular  
288 measurements and operational procedures, synthesize the available knowledge, and develop  
289 recommendations to improve GRUAN measurements and operations. The TTS and WG-  
290 GRUAN shall confer regularly to evaluate the current status of GRUAN observations, to identify  
291 weaknesses, and to incorporate new scientific understanding into GRUAN. The expertise of  
292 these teams shall also be used to support the Lead Centre in guiding individual sites through  
293 changes in instrumentation and operating procedures without impacting long-term measurement  
294 time series.

295 The GRUAN Lead Centre shall identify sites where instrument operators need training, re-  
296 training, and organise cost-efficient training courses for the network at appropriate locations, as  
297 advised by the appropriate TTS, to encourage uniformity of instrument operation between sites.  
298 The Lead Centre may liaise with National Metrological Institutes in this regard.

299 All activities associated with the implementation of GRUAN are the responsibility of the  
300 institution/organization hosting the GRUAN site and should, as far as possible, be met through  
301 national funding. To best serve the needs of the climate monitoring and research communities, it  
302 is essential that GRUAN is cognizant of the evolving science that drives the measurements and  
303 accuracy of the GRUAN data. The ozonesonde instrumentation deployed and the observing  
304 schedules may differ between sites, as agreed with WG-GRUAN as part of the site assessment

305 and certification process, but the methods of observation used with the main observing systems  
306 are expected to be uniform between all GRUAN sites.

## 307 **1.5. Links to partner networks and satellite-based measurement** 308 **programmes**

309 In the original charter for GRUAN (GCOS-92) it is stated that ‘where feasible, the GRUAN sites  
310 should be co-located and consolidated with other climate monitoring instrumentation’. GRUAN  
311 Ozonesonde Programmes shall not be run in isolation of existing ozonesonde networks and  
312 GRUAN is not intended to replace existing networks. GRUAN Ozonesonde Programmes are  
313 likely to operate in the framework of existing networks such as the Network for the Detection of  
314 Atmospheric Composition Change (NDACC) and SHADOZ (Southern Hemisphere ADditional  
315 OZonesondes), and to leverage off the expertise available in these networks and e.g. through the  
316 GAW (Global Atmosphere Watch<sup>2</sup>) scientific advisory group for ozone. As a result, close and  
317 regular coordination between the governing bodies of these networks and with the WG-GRUAN  
318 and GRUAN TTR+AM is required. This coordination can be achieved by having members of the  
319 WG-GRUAN and TTR+AM attend steering group meetings of partner networks and by inviting  
320 co-chairs or steering group members from partner networks to attend WG-GRUAN and GRUAN  
321 TTR+AM meetings.

322

323 Where an existing ozonesonde measurement system meets the operational requirements of  
324 GRUAN, the first priority is to encourage that site to join GRUAN. In such cases operational  
325 requirements should be optimized to meet the needs of both parties.

### 326 **1.5.1. NDACC (Network for the Detection of Atmospheric Composition Change)**

327 NDACC comprises more than 70 remote-sensing research sites for observing and understanding  
328 the physical and chemical state of the stratosphere and upper troposphere and for assessing the  
329 impact of stratospheric changes on the underlying troposphere and on global climate. A number  
330 of NDACC sites fly ozonesonde and NDACC has a standing working group on ozonesondes,  
331 water vapor sondes, and aerosol sondes.

### 332 **1.5.2. GAW (Global Atmosphere Watch)**

333 GAW is as a coordinated network of observing stations, associated facilities and related  
334 scientific assessment activities, and supplies basic information to be used by policy-makers  
335 [Global Atmosphere Watch Guide, GAW Report No.86, 1993]. As a major component of GAW,  
336 the global network of ozone sounding stations provides the longest time series of the vertical  
337 ozone distribution between surface and 30-35 km altitude [GAWSIS,  
338 <http://www.empa.ch/gaw/gawsis>].

### 339 **1.5.3. Atmospheric Radiation Measurement (ARM) Programme**

340 The goal of the U.S. Department of Energy ARM programme is to study changes in climate, land  
341 productivity, oceans or other water resources, atmospheric chemistry, and ecological systems  
342 that may alter the capacity of the Earth to sustain life. This includes improving the atmospheric

---

<sup>2</sup> [http://www.wmo.ch/web/arep/gaw/gaw\\_home.html](http://www.wmo.ch/web/arep/gaw/gaw_home.html)

343 data sets used in regional and global climate models. A primary objective of the ARM user  
344 facility is to improve scientific understanding of the fundamental physics related to interactions  
345 between clouds and radiative processes in the atmosphere.

346 A dedicated Data Quality (DQ) Office provides ARM with a number of tools to ensure the high  
347 quality of the collected data. The potential use of these tools in GRUAN must be explored to  
348 ensure network-wide homogeneity of the GRUAN ozonesonde measurements. The ARM DQ  
349 Office has developed a suite of sophisticated data quality visualization tools that may be of  
350 interest to GRUAN Ozonesonde Programmes.

#### 351 **1.5.4. SHADOZ (Southern Hemisphere Additional Ozonesondes)**

352 SHADOZ (Southern Hemisphere Additional Ozonesonde) is a project to augment and archive  
353 ozonesonde data from over a dozen tropical and sub-tropical sites and has become the central  
354 repository for vertical profiles of ozone in the tropics/sub-tropics. Prior to the creation of  
355 SHADOZ, tropical ozonesonde data were accessible via campaigns or collaborative associations  
356 with specific operating site representatives. Started in 1998 by NASA's Goddard Space Flight  
357 Center, and other US and international co-investigators, SHADOZ is an important tool for  
358 equatorial tropospheric ozone research. The rationale for SHADOZ is to: (1) validate and  
359 improve model and remote sensing techniques for estimating tropical ozone, (2) contribute to  
360 climatology and trend analyses of tropical ozone and (3) provide research topics to scientists and  
361 educate students, especially in participating countries [Thompson et al., 2003a; 2003b, 2004,  
362 2007, 2012]. SHADOZ is envisioned as a data service to the global scientific community by  
363 providing a central public archive location via the internet: <http://croc.gsfc.nasa.gov/shadoz>.  
364 SHADOZ data are mirrored at the Aura Validation Data Center (AVDC) and are deposited to  
365 WOUDC. While the SHADOZ website maintains a standard data format for the archive, it also  
366 informs data users of the differing sites' preparation techniques and data treatment. Data from  
367 launches from various SHADOZ supported field campaigns, such as, the Indian Ocean  
368 Experiment (INDOEX), Sounding of Ozone and Water in the Equatorial Region (SOWER) and  
369 Aerosols99 Atlantic Cruise are also available.

#### 370 **1.5.5. WOUDC (World Ozone Ultraviolet Data Centre)**

371 WOUDC operates under the auspices of the WMO/GAW programme to archive ozone and  
372 ultraviolet in-situ instrument data. Data is contributed to WOUDC at no cost and provides an  
373 independent storage and backup of instrument data. Like SHADOZ, WOUDC is a web-based,  
374 public access archive ([www.woudc.org](http://www.woudc.org)) and provides enhanced user search capabilities and  
375 visualizations. The WOUDC gets guidance from the WMO Science Advisory Groups (SAGs)  
376 for issues related to both ozone and UV.

377

#### 378 **1.5.6. Link to satellite-based measurement programmes**

379 Ozonesonde measurements have historically provided a key data set for validating satellite-based  
380 measurements of ozone. GRUAN Ozonesonde Programmes, with their well characterized  
381 measurement uncertainties and network wide homogeneity are expected to provide a database of  
382 vertically resolved ozone that will be essential for validating satellite-based measurements of the  
383 vertical distribution of ozone. Because the GRUAN ozonesonde measurements are likely to  
384 serve a wide range of end-users within the satellite measurement community, WG-GRUAN and

385 TTR+AM members shall be assigned to liaise with key clients within the satellite community to  
386 ensure that GRUAN ozonesonde data products are tailored, where possible, to best meet the  
387 needs of this community. Once GRUAN ozonesonde data sets are available, pilot studies on  
388 enhanced combined data sets using these reference measurements e.g. generating site  
389 atmospheric state best estimates (SASBEs) for ozone, need to be undertaken. The GRUAN  
390 ozonesonde measurements provide an essential database for removing offsets and drifts between  
391 separate satellite-based measurement series within the limitations imposed by the uncertainties  
392 on the GRUAN ozonesonde measurements.

## 393 2 GRUAN OZONESONDE TECHNIQUES AND 394 MEASUREMENT PRINCIPLES

395 This section provides the GRUAN Ozonesonde Programmes and user community with essential  
396 knowledge of the way ozonesondes measure profiles of ozone. For further comprehensive  
397 reviews of the ozonesonde measurement technique, the reader should refer to the publications  
398 mentioned in this section.  
399

400 Ozonesondes are small, lightweight balloon-borne instruments that use an electro-chemical  
401 technique to make in situ measurements of ozone from the surface of the Earth to an altitude  
402 determined by balloon burst, typically 30 to 35 km [Smit et al., 2002]. The sonde is interfaced to  
403 a standard meteorological radiosonde for transmission of the data to the ground and is usually  
404 flown together with the radiosonde as part of the same package. The package is carried aloft by a  
405 rubber balloon similar to that used for radiosonde measurements, though in this case a 1000-  
406 1200 g balloon is typically used rather than the standard 300 g meteorological balloon. The  
407 package ascends through the atmosphere at  $\sim 6 \text{ m.s}^{-1}$  and, with a measurement frequency of  $\sim 2$   
408 seconds, results in a vertical resolution of less than 15 m. Ozonesondes constitute the most  
409 important data source with long term-data coverage for the derivation of ozone trends with  
410 sufficient vertical resolution, particularly in the important, climate sensitive, altitude region  
411 around the tropopause.

412  
413 As defined in GCOS-171:

414 “A reference measurement result typically arises from a defined measurement procedure that  
415 involves standards traceable to national or international standards as maintained at National  
416 Metrological Institutes (NMIs). For GRUAN, a reference measurement is one where the  
417 uncertainty of the calibration and the measurement itself is carefully assessed. This includes the  
418 requirement that all known biases have been identified and corrected, and, furthermore, that the  
419 uncertainty on these bias corrections has also been determined and reported. An additional  
420 requirement for a reference measurement is that the measurement method and associated  
421 uncertainties should be accepted by the user community as being appropriate for the  
422 application.”  
423

424 To produce GRUAN ozonesonde reference measurements, mandatory and recommended  
425 processing procedures have been established such that the ozonesonde data products derived  
426 shall be reproducible at any time in the future. Section 2 describes the data processing procedures  
427 required for each component of the ozonesonde measurement technique. The GRUAN  
428 Ozonesonde Programmes and centralized ozonesonde data processing facility shall apply these  
429 procedures to create the standard reference GRUAN ozonesonde data product (see Sections 3.5 -  
430 3.7).  
431

432 As of the time of the development of this Technical Document, the Electrochemical  
433 Concentration Cell (ECC) sonde (Komhyr, 1969) is the only type of ozonesonde being flown and  
434 therefore this document focusses solely on SOPs for the ECC sonde type. Two other types of  
435 sondes, namely the Brewer-Mast (BM) sonde (Brewer and Milford, 1960) and the Japanese  
436 manufactured Carbon Iodide (CI) sonde (Kobayashi and Toyama, 1966) are no longer being

437 flown operationally. In the last decade long-term BM sonde sites have changed to ECC sondes.  
 438 The homogenization of time series that use BM and ECC sondes at the Uccle, Belgium, site has  
 439 been undertaken by De Backer [1999] using results from dual BM/ECC sonde launches [De  
 440 Backer et al., 1998] – see also Section 7.2 on the use of transfer functions for homogenizing time  
 441 series that include BM and ECC sondes. Dual flight campaigns at the Payerne, Switzerland, site  
 442 showed no detectable differences between their BM and ECC sondes [Stübi et al., 2008]. Since  
 443 the late 2000s, Japanese sites have switched from using CI sondes to using ECC sondes. While  
 444 Nakamura et al. [2008] conducted inter-comparison studies for CI and ECC sondes, transfer  
 445 functions between the two sensors have not yet been derived.

## 446 2.1 The Ozonesonde Measurement

447 The ECC instrument consists of a non-reactive teflon gas-sampling pump connected to an ECC  
 448 ozone sensor, and an electronic interface that connects the ozone sensor to a radiosonde for data  
 449 telemetry (see Figure 1 of Komhyr, 1995). The instrument is encased in a polystyrene  
 450 weatherproof box during flight. Measurements of ozone partial pressure, the sonde’s pump  
 451 temperature, motor voltage and current, air temperature, air pressure and humidity are  
 452 transmitted to a ground receiving station. Winds derived from GPS-enabled measurements  
 453 became available in the early 2000s.

454  
 455 The ECC sensor measures ozone using iodine/iodide electrode reactions [Vetter, 1967]. Two  
 456 platinum electrodes are immersed in separate cathode and anode chambers, also called half cells,  
 457 of differing concentrations of potassium iodide (KI) solution. The anode cell contains a solution  
 458 saturated with KI. Both cells contain an equal concentration of potassium bromide (KBr) and a  
 459 phosphate buffer to maintain a neutral pH. An ion bridge connecting the two chambers, allows  
 460 ions to flow between the two cells but prevents mixing, thereby preserving their respective  
 461 concentrations.

462  
 463 Ambient air containing ozone ( $O_3$ ) is pumped into the cathode cell and reacts with iodide ( $I^-$ ) to  
 464 form iodine ( $I_2$ ) based on the aqueous reaction:

466  
 467 To maintain electrochemical equilibrium iodine is converted back to iodide on the platinum  
 468 electrode resulting in the release of two electrons by the following reactions:

472  
 473 Rxn 2 and 3 are rate determining reactions and result in the transfer of ion to the electrode  
 474 surfaces. An equilibrium exists between  $I_2$  and  $I_3^-$  (tri-iodide) when the concentrations of  $I^-$  are  
 475 kept constant.

476  
 477  
 478  
 479  
 480

481 As a result of the reactions detailed above, each ozone molecule entering the sensor causes two  
482 electrons to flow through the ECC's external circuit, which is measured as a current. The  
483 resulting electrical current is linearly proportional to the concentrations of ozone in the sampled  
484 air. The electrochemical technique assumes no secondary reactions take place and a 1:1  
485 stoichiometric relationship of the I<sub>2</sub>:O<sub>3</sub> ratio is maintained. The relationship between ozone and  
486 the electrical current (measured in μA) is computed using:

487  
488 Eqn. 1 
$$P_{O_3} = 4.307 \times 10^{-4} (I_M - I_{BG}) T_P \Phi \psi$$

489  
490 where

491  
492 P<sub>O<sub>3</sub></sub> = Ozone partial pressure (mPa)

493 I<sub>M</sub> = Cell current (μA)

494 I<sub>BG</sub> = Cell background current (μA)

495 T<sub>p</sub> = Ozonesonde pump temperature (K)

496 Φ = Pump flow rate (s/100cm<sup>3</sup>)

497 ψ = Pump flow conversion efficiency (1/pump flow correction factor, unitless)

498  
499

500 The constant, 4.307×10<sup>-4</sup>, is the half ratio of the ideal gas constant to Faraday's constant.  
501 Measurement techniques and uncertainty estimates for each variable in Eqn. 1 are reviewed  
502 below. The cell current, I<sub>M</sub>, and pump temperature, T<sub>p</sub>, are in situ measurements while the cell  
503 background current, I<sub>B</sub>, and flow rate, Φ, are measured during pre-flight preparations under  
504 ambient laboratory conditions and are assumed to remain constant throughout the flight. While it  
505 is preferable that the conversion efficiency, ψ, is determined for each flight, unless automated,  
506 this can be very time consuming and as a result ψ values are usually taken from a table of pump  
507 flow measurements made at varying low pressures to account for the decrease in pump efficiency  
508 at low temperatures. Uncertainties on ψ are expected to be smaller if they are determined  
509 individually for each flight rather than taken from a table (which needs to also provide the  
510 statistical uncertainty on the ψ values). ψ values vary with ECC sensor type and are further  
511 explained in Section 2.5.

512

513

## 514 **2.2 Measuring the background current**

515 The background current (I<sub>B</sub>) is the residual current measured by the sonde when sampling ozone-  
516 free air. Conventional processing of the sonde telemetry assumes that the background current  
517 remains constant during flight and the same assumption is made when processing ozonesonde  
518 data within GRUAN. As seen in Equation 1, the background current is subtracted from the ECC  
519 sensor current to infer the ozone partial pressure. In the initial conditioning procedure, both  
520 cathode and anode cells are filled with sensing solution and stored for no less than 3 days prior to  
521 launch to reduce the background current and improve the sensor response time (i.e. the time it  
522 takes for the sensor electronics to respond to a change in ozone concentration) [Kohmyr, 1986;  
523 1997]. Kohmyr and Harris [1971] show that the background current decreases after the ECC is  
524 stored for several days while charged with their working solutions; they call this process 'self-  
525 cleaning'.

## GRUAN protocols for measuring background current

GRUAN follows the WMO/GAW SOPs for background current measurement [Smit et al. 2014] requiring three background measurements as detailed below.

1. Initial conditioning, i.e. the conditioning procedures when the sensor is first taken out of the box, shall occur no less than 3 days before the ozonesonde flight. As this is the minimum acceptable period for the background current to decrease to within the thresholds defined below.
2. Day of flight preparations shall be made no more than 7 days after the initial conditioning. If more than 7 days have elapsed, then the cathode and anode chambers must be replaced with fresh solution and initial conditioning procedures must be repeated. Dates of repeated solution change shall be documented in the metadata for collection by the GRUAN RSLaunchClient (addressed in Section 3.6).
3.  $I_{B0}$  is recorded when the calibration/ozonizer unit is used to run ozone-free air through the sensor, filled with fresh solution, for 10 minutes.
  - a. Following BESOS procedures [Deshler et al, 2008] ozone-free air is run through the sensor until the background no longer drops or until the background current is less than  $0.05 \mu\text{A}$ .
  - b. If the background current does not drop below  $0.05 \mu\text{A}$  after 20 minutes, the solutions must be changed and the background current measurement repeated. If, after another 20 minutes, the background does not fall below  $0.05 \mu\text{A}$  the final value should be recorded in the metadata check list, regardless. Ideally, these steps should bring  $I_{B0}$  below the  $0.05 \mu\text{A}$  threshold value.
4.  $I_{B1}$  is recorded after the response time measurement, i.e. the time required for the sensor current to drop from  $4 \mu\text{A}$  to  $1.5 \mu\text{A}$ , and after an additional 10 minutes of ozone-free air has been flushed through the cells. This value may be higher than  $I_{B0}$ .
5.  $I_{B2}$  is recorded prior to launch with the ozonesonde intake tube fitted to an ozone destruction filter. This value may be higher than  $I_{B0}$ .

All three background currents shall be recorded by the GRUAN RSLaunchClient (see Section 3.6). Historically, operators have used  $I_{B2}$  as the value for  $I_B$  in Eqn. 1. In recent years other methods of applying background currents have been employed, such as the minimum of the three background currents [Ryan Stauffer/Penn State, personal communication], a laboratory determined  $I_B$  [Holger Vömel/NCAR, personal communication], or  $I_B$  set to an upper limit value for those background currents that exceed a maximum threshold based on average  $I_B$  measured under optimal laboratory conditions [Bryan Johnson/NOAA, personal communication]. For the GRUAN central processing of ozonesonde flight data,  $I_{B0}$  shall be used as the background current for the following reasons:

- The quality of the ozone destruction filter under launch conditions (non-laboratory controlled environment) used to measure  $I_{B2}$  cannot be assured to be uniform between flights which introduces a source of random uncertainty which cannot be easily quantified [Reid et al., 1996]. This is particularly the case when ozonesondes are flown in

573 the tropics where high humidity affects the ozone removal efficiency of the filter  
574 [Newton et al., 2016].

- 575 • The use of  $I_{B2}$  as the background current is likely an overestimate of the true background  
576 current which then leads to an underestimate of the ozone partial pressure. In particular,  
577 tropical and polar ozone profiles are strongly influenced by the magnitude of the  
578 background current [Reid et al, 1996; Vömel and Diaz, 2010; Newton et al.; 2016].  
579 Under mid-latitude and tropical conditions, Smit et al. [2014] show that background  
580 currents ranging from 0.05 to 0.1  $\mu\text{A}$  contribute 10-20% and 20-40%, respectively, to the  
581 measured cell current in the free troposphere.
- 582 •  $I_{B1}$  is excluded as an option since it can be biased high. The 10-minute flow of ozone-free  
583 air after ozone exposure is arbitrary and likely not representative of the true background  
584 current [Thornton and Niazy, 1982; Vömel and Diaz, 2010; Bryan Johnson/NOAA,  
585 personal communication]. Laboratory experiments by Vömel and Diaz [2010] identified  
586 the decay of the cell current after exposure to ozone and showed that the current does not  
587 relax to pre-ozone values after 10 minutes of ozone-free air and that a much longer period  
588 of time (hours) is required to approach initial values. The BESOS field campaign  
589 [Deshler et al, 2008] found similar enhancements in the background current after ozone  
590 exposure. The elevated cell currents indicate a slower decay in the sensor response  
591 suggesting that the flushing of ozone-free air for 10 minutes through the cells is not long  
592 enough to reduce the cell current to pre-ozone exposure values.
- 593 • A field study conducted by Newton et al. [2016] found stable low background currents  
594 when the ozone exposure test during the day of flight preparations was ignored.  
595

596 Using  $I_{B0}$  ensures that background currents are measured under stable, controlled laboratory  
597 conditions where uncertainties can be more robustly quantified.

598  
599 When  $I_{B0}$  exceeds 0.05  $\mu\text{A}$  the following steps shall be taken:

- 600 1. If a solution change, followed by a reasonable length of time running zero ozone air does  
601 not bring  $I_{B0}$  below 0.05  $\mu\text{A}$ , then the minimum of  $I_{B0}$ ,  $I_{B1}$ , and  $I_{B2}$  shall be used as  $I_B$ .
- 602 2. If the minimum background current is still greater than 0.05  $\mu\text{A}$ , then an  $I_B$  value of 0.05  
603  $\mu\text{A}$  must be used. Smit et al. [2012] estimated that properly measured background  
604 currents since the mid-1990s should be less than 0.05  $\mu\text{A}$  in the current generation of  
605 ECC sensors. Based on JOSIE results, 0.05  $\mu\text{A}$  is an upper limit to  $I_{B0}$  [Smit et al., 2007].  
606

607 GRUAN will apply a constant background current correction following WMO/ASOPOS  
608 guidelines [Smit et al. 2012; 2014]. Thornton and Niazy [1982] showed that sensors in the early  
609 1980s exhibited negligible sensitivity to  $\text{O}_2$  allowing the background current to be treated as a  
610 constant. More recent studies support this finding [Smit et al, 1994; Reid et al. 1996; Newton et  
611 al., 2016]. Vömel and Diaz, [2010] introduced a modified ozone partial pressure equation that  
612 takes into account the excess ozone response due to the buffering of the solution. They measured  
613 uncertainties of 0.005  $\mu\text{A}$  for a 1% full buffer solution and 0.009  $\mu\text{A}$  for a 0.5% half buffered  
614 solution.

615

616 Any changes to the treatment of ozonesonde background currents to those described above must  
617 be founded on JOSIE-type experiments, followed by rigorous assessment.

618 **2.3 Effects of different sensing solutions and ozonesonde type**

619

620 While the fundamental chemistry and operating mechanics of the ECC sonde have remained  
 621 largely unchanged, the KI solution concentrations have varied over the past decades in attempts  
 622 to improve the measurement accuracy and stability. Inter-comparison campaigns and laboratory  
 623 studies have been conducted to evaluate the ECC sonde performance using different sensing  
 624 solution recipes with current sensor types [Hilsenrath et al., 1986; Boyd et al., 1998; Johnson et  
 625 al., 2002; Smit et al., 2007; Deshler et al, 2008]. The JOSIE studies have shown that the  
 626 precision and accuracy is strongly dependent on the ozonesonde type and solution [Smit et al.,  
 627 2007]. JOSIE experiments reveal that differences in instrument construction between SPC and  
 628 ENSCI significantly impacts the ozonesonde performance.

629

630 A variety of sensing solution concentrations and pH buffers are typically used in ECC sondes  
 631 (see Table 2.3.1) The anode solutions are prepared by saturating the cathode solution with KI  
 632 crystals.

633

634 Table 2.3.1

Sensing Solution Type	KI, g/L	pH Buffer, g/L	
		NaH <sub>2</sub> PO <sub>4</sub> •H <sub>2</sub> O	Na <sub>2</sub> HPO <sub>4</sub> •12H <sub>2</sub> O
1.0% KI, full buffer	10	1.25	5.0
0.5% KI, half buffer	5	0.625	2.5
2.0% KI, no buffer*	20	0	0
1.0% KI, 1/10 <sup>th</sup> buffer*	10	0.125	0.5

635

\* Used at NOAA-led ozonesonde stations only.

636

637 The 1.0% KI with full pH-buffer is the conventional cathode sensing solution used for the  
 638 ozonesonde types SPC-4A, -5A, and -6A [Science Pump Corporation manual, 1996]. Until  
 639 1996, ENSCI advocated using the 1.0% solution formula but then switched to recommending a  
 640 0.5% KI with half pH-buffer sensing solution formula after 1996 [ENSCI Corporation manual,  
 641 1996]. Johnson et al. [2002] introduced the 2.0% non-pH-buffered solution with no KBr that all  
 642 NOAA-led ozonesonde stations used for a period of almost 10 years in the late-1990s to mid-  
 643 2000s until switching to a modified 1.0% KI solution using a 1/10<sup>th</sup> buffer cathode sensing  
 644 solution recipe. The 2.0% no-buffer solution formula is no longer recommended. The 1.0% KI  
 645 with 1/10<sup>th</sup> buffer sensing solution is a relatively new formula and has yet to be included in  
 646 JOSIE-led evaluation studies. Until that time, only the 0.5% half buffer and 1.0% full buffer  
 647 sensing solutions shall be used in GRUAN, following WMO/GAW recommendations and as  
 648 detailed in Table 2.3.2.

649

Manufacturer/Model	Solution concentration
SPC 6A	1%, full buffer
ENSCI Z, 2Z	0.5%, half buffer

650

Table 2.3.2 Table of ECC sensors and solution pairing.

651

652 The JOSIE-2000 experiment focused on combinations of ECC sensors and sensing solution  
 653 types to determine the optimal pairing when compared with the world standard UV-photometer.

654 Results show a reduction in biases for SPC sondes when using the 1.0% KI solution with full  
655 buffer pair and for ENSCI sondes that use a 0.5% KI solution with half buffer solution. JOSIE  
656 results showed that the SPC/1% and Z/0.5% pairings behave similarly, i.e. measurement  
657 differences are within 1.0%.

658

### 659 **Homogenizing records that use different sensing solutions**

660

661 GRUAN recognizes that ECC sensor technology is constantly evolving as solution recipes are  
662 fine-tuned to optimize performance and that not all sites coming into GRUAN will operate with  
663 the same ECC sensor/solution pairing detailed in Table 2.3.2, e.g. an existing site may continue  
664 to use an obsolete sensing solution (e.g. 2% unbuffered) to avoid potentially introducing a  
665 discontinuity in the measurement time series, especially if transfer functions have not yet been  
666 tested and established.

667

668 Ideally, the ECC sensor and solution type should have a legacy of using one of the two  
669 combinations defined in Table 2.3.2. Sites using an ECC sensor/solution type outside of the  
670 SPC/1.0% or ENSCI/0.5% pairing should be homogenized with the application of transfer  
671 functions (see Section 7.2). Systematic biases between ozone measurements typically result from  
672 ECC sensors of the same manufacturing type being operated with different sensing solution  
673 concentrations. For ozonesonde sites performing long-term measurements, a change of the  
674 sensing solution concentration or ECC-sensor type can introduce a  $\pm 5\%$  change, or more, in their  
675 ozone records, affecting the determination of ozone trends [Smit et al., 2014].

676

677 To support the homogenization of ozonesonde measurement series whose homogeneity is  
678 compromised by historical changes in sensing solutions, the ASOPOS working group, as part of  
679 the SPARC/IGACO-O3/IOC/NDACC initiative, has established transfer functions based on  
680 JOSIE experiments [Smit et al., 2007] for a variety of ECC sensor type and solution strength  
681 combinations. Their use allows homogenization of long-term records to conform to either an  
682 SPC/1.0% or ENSCI/0.5% sensor/solution pairing (Refer to Section 8.1.2, Table 3 of Smit et al.  
683 [O3S-DQA, 2012] for conversion factors). Section 7.2 provides further details and processing  
684 protocols involving transfer functions.

685

686 While GRUAN Ozonesonde Programmes should commit to using the same ECC sensor and  
687 solution type for the lifetime of the measurement programme, changes may be considered if

688

- 689 • Sufficient justification, as determined by the GRUAN Lead Centre and the centralized  
690 GRUAN ozonesonde data processing facility, is provided for the proposed change. A  
691 balance must be found between GRUAN Ozonesonde Programmes being responsive to  
692 the latest technological and scientific progress in ozonesonde measurement techniques  
693 and observational requirements, and the importance of avoiding discontinuities in the  
climate data record.

694

- 695 • A new model is developed or a new manufacturer enters the ECC market that  
696 recommends a new sensing solution recipe.

697

698 Changes in ozonesonde working solutions must be managed through an appropriate change  
management programme whereby the necessary tests, laboratory studies, and dual sonde launch

699 campaigns are conducted to characterize any systematic biases, and their uncertainties, in the  
700 stoichiometry and response times at all pressure altitudes (see Section 6 on the uncertainty  
701 budget). Sites undergoing such change management shall also participate in developing transfer  
702 functions required to maintain the homogeneity in the data record.

703  
704

705 Ozonesonde expertise outside of GRUAN shall also be used to support the Lead Centre in  
706 guiding individual sites through changes in instrumentation without impacting long-term  
707 measurement time series.

708

## 709 **2.4 Measuring pump flow rate**

710 A common procedure in the ECC conditioning is to use the soap bubble flowmeter method to  
711 measure the volumetric flow rate of the pump,  $\Phi$  [sec/100ml]. The required equipment and set-  
712 up are described in the ENSCI and SPC manuals [DMT manual, Appendix D, 2014; SPC manual  
713 Section 3.2.1, 1999]. While the ECC is charged with solution and the air pump is operating, the  
714 cathode outtake tube is connected to the flowmeter. The air flowing from the ECC pump into the  
715 burette allows soap bubbles to rise up the burette. As a single soap bubble rises, a handheld  
716 stopwatch is used to determine the time to displace that soap bubble 100 ml. Several flow rates  
717 are calculated and the mean is assigned as the final  $\Phi$  applied in Equation 1. The uncertainty of  
718 the flow rate is small, generally within  $\pm 1\%$  [Smit et al., 2014].

719

720 The GRUAN procedure for determining pump flow rate is as follows:

721

722 1. The flowmeter equipment provided by ENSCI and SPC is standard and reasonably identical.  
723 GRUAN will accept either.

724

725 2. GRUAN acknowledges that the soap bubble solution recipe varies among manuals and  
726 operators and requires only that the same recipe is used throughout the lifetime of the  
727 measurement record.

728

729 3. The measurement of the flow rate shall be made five times as required by WMO/GAW and  
730 implemented in most SOPs.

731 i. Flow rates that differ by 2 sec/100ml or more from the median after measuring the  
732 flow rate five times should be redone.

733 ii. Mean  $\Phi$  should be between 26 and 32 sec/100ml.

734 • Lower and upper limits are chosen by consulting pump flow rate ranges  
735 found in the SPC manual [1999] and Smit et al., [2014].

736 • If the mean  $\Phi$  is not within the acceptable range, this must be reflected in a  
737 the setting of an appropriate data QA/QC flag.

738

739 4. As recommended by WMO/GAW, flow rates must be measured on the day of the flight.

740

741 5. Lab temperature, relative humidity, and pressure should be recorded at the time the flow rate  
742 measurements are taken to correct for the evaporation of the soap bubble solution (see  
743 Komhyr et al. [1995], Johnson et al. [2002], and Smit et al., [2014] and Section 8.4).

744 GRUAN Ozonesonde Programmes must use equation 17 from Smit et al. [2012] to calculate  
745 the pump flow rate correction factor,  $C_{PH}$ . WMO/GAW defines  $C_{PH}$  as  
746

747 Eqn 2.4.1 
$$C_{PH} = \left[ 1 - \frac{RH_{Lab}}{100} \right] \cdot \frac{P_{H2O,Sat}(T_{Lab})}{P_{Lab}}$$

748 where,  $P_{H2O,Sat}$  is the saturation vapor pressure under laboratory conditions, i.e.  $P_{Lab}$ ,  $T_{Lab}$ , and  
749  $RH_{Lab}$ .  $C_{PH}$  is applied to the mean  $\Phi$  with the expectation that this has a negligible impact on the  
750 uncertainty calculations.  
751

752  
753 6. The pump flow rate must also be corrected for the temperature difference between the  
754 internal pump base temperature and the ambient room temperature.  $C_{PL}$  is defined as  
755

756 Eqn 2.4.2 
$$C_{PL} = \frac{T_P - T_{Lab}}{T_{Lab}}$$

757  
758 WMO/GAW reports  $(T_P - T_{Lab})$  are on the order of +2K with an uncertainty of  $\pm 0.5K$ .  
759

760 7. The corrected pump flow rate is then expressed as:

761  
762 Eqn 2.4.3 
$$\Phi_{Final} = [1 + C_{PL} - C_{PH}] \cdot \Phi$$

763  
764 Section 6.3 addresses the flow rate uncertainty and its contribution to the ozone measurement  
765 uncertainty.  
766

## 767 **2.5 Estimating degradation in pump efficiency**

768 It has been well documented that the efficiency of the ECC pump decreases at high altitudes  
769 [Komhyr, 1967; 1969; 1986; et al. 1995; Johnson et al., 2002; Smit et al., 2014]. Johnson et al.  
770 [2002], and references therein, cite pump leakage, dead volume in the piston pump, and back-  
771 pressure exerted on the pump by the cell solution as main causes of pump efficiency loss at low  
772 pressures. Experiments reveal that the pump flow rate,  $\Phi$ , measured at the ground is constant up  
773 to 100 hPa and decreases steadily to the top of the atmosphere. This is true for the pumps used in  
774 both SPC and ENSCI ozonesondes.

775  
776 Calculated ozone partial pressures must therefore include a correction for the effects of pump  
777 efficiency loss. From Equation 1 (in Section 2.1), the pump flow conversion efficiency,  $\Psi$   
778 (1/pump correction factor), takes into account the efficiency loss in  $\Phi$  as a function of pressure.  
779 Empirical averages obtained from various lab techniques have yielded pump correction factors  
780 (PCFs; Komhyr [1986]; Komhyr et al. [1995]). The two most widely used PCFs are shown in  
781 Table 2.5.1. Table 2.5.1 PCFs have been calculated based on SPC ECC type and models older  
782 than SPC 6A. The sample sizes are small (e.g. K95 N = 13) and it is recommended that  
783 laboratory studies be conducted to obtain much larger sample sizes of the various ECC models  
784 currently in use to verify or update the pump efficiency corrections and their uncertainties.  
785

Pressure [hPa]	Komhyr, 1986 (K86)	K86 uncertainty, $\Delta\Psi$	Komhyr et al., 1995 (K95)	K95 uncertainty, $\Delta\Psi$
Sfc-100	1.000	1.000	1.000	1.000
100	1.007	$\pm 0.005$	1.007	$\pm 0.005$
50	1.018	$\pm 0.006$	1.018	$\pm 0.005$
30	1.022	$\pm 0.008$	1.029	$\pm 0.008$
20	1.032	$\pm 0.009$	1.041	$\pm 0.012$
10	1.055	$\pm 0.010$	1.066	$\pm 0.023$
7	1.070	$\pm 0.012$	1.087	$\pm 0.024$
5	1.092	$\pm 0.014$	1.124	$\pm 0.025$
3	1.124	$\pm 0.025$	1.241	$\pm 0.043$

787 Table 2.5.1 Pump corrections factors (PCF) with 1-sigma uncertainties. PCF values are taken  
788 from the GAW Report No. 201, Table 3-3 [Smit et al., 2014].

789

790 Following the recommendations of WMO/GAW report 201 [Smit et al., 2014], GRUAN  
791 Ozonesonde programmes shall use the K86 PCFs for SPC ozonesondes and K95 PCFs for  
792 ENSCI ozonesondes as listed in Table 2.5.1. PCFs between tabulated values must be interpolated  
793 on a log pressure scale with 2<sup>nd</sup> order polynomial interpolation. Ideally GRUAN should use PCFs  
794 derived individually for each sonde. As briefly mentioned above, obtaining PCFs for each sonde  
795 should result in smaller uncertainties on PCFs over using tabulated values which represent mean  
796 values across multiple samples. However, these measurements are time consuming, require  
797 additional hardware and, if made in a non-standard way, could introduce inhomogeneities across  
798 the network. See e.g. Figure 7 from Johnson et al. [2002] that shows a significant spread of PCF  
799 values that are based on different measurement techniques and different ECC types and models.  
800 Methods for calculating PCFs are not standardized in the ENSCI and SPC manuals, nor  
801 considered in the WMO/ASOPOS recommendations. While it would be best practice for  
802 GRUAN to use PCFs specific to current models, i.e. SPC 6A or ENSCI Z ECC, based on  
803 statistically appropriate sample sizes, the resultant look-up tables do not currently exist. GRUAN  
804 therefore encourages peer-reviewed laboratory studies that will produce PCFs, with associated  
805 uncertainties, specific to manufacturer type and model. Until such results become available,  
806 GRUAN shall use the WMO/GAW recommended values tabulated above.

807

## 808 2.6 Measuring pump temperature

809 The temperature of the ozonesonde pump,  $T_p$ , is required in the calculation of the ozone partial  
810 pressure (see Equation 1., Section 2.1) to account for the temperature of the air flowing through  
811 the pump. Over time, the location of the thermister used to measure the pump temperature has  
812 changed, potentially introducing inhomogenieties into the sounding record [Smit et al., 2014].  
813 Smit et al. [2014] has identified five configurations of  $T_p$  measurements based on the placement  
814 of the thermister (see Table 2.6.1) and has characterized their uncertainty relative to the current  
815 placement of thermisters in modern ECC sondes which is inside the pump and is referred to as  
816 the internal pump temperature (see Case 5 in Table 2.6.1).

817

818

819 Table 2.6.1

Case	Time Period	Location	Name	Sonde Types	Notes
1	1960- end 1980s	Bottom of circuit board	Box Temperature	SPC 2A, 3A, 4A	Analog sondes
2	1990s	Suspended in the styrofoam box in the vicinity of the pump	Box Temperature	SPC 5A	Start of digital sounding systems. Behaves as in Case 3
3	1990s	Taped thermister at the pump base	External Pump Temperature	SPC 5A	
4	1990s	Epoxied at the pump base	External Pump Temperature	SPC 5A	Behaves like Case 1
5	> 1995	Mounted inside the pump body, close to the piston	Internal Pump Temperature	ENSCI Z & 2Z, SPC 6A	Current generation ECC soundings

820  
821 Smit et al. [2014] considers the correct or 'true'  $T_p$  as the pump temperature measured in the  
822 vicinity of the moving piston,  $T_{piston}$ . Based on Komhyr and Harris [1971] and JOSIE 2000 lab  
823 experiments [Smit et al., 2007], empirical pressure dependent equations have been formulated to  
824 adjust pump temperatures from Cases 1 through 4 to an internal pump based temperature (Case  
825 5). Internal pump temperatures are considered to be the best approximation to the 'true'  $T_p$ .  
826 Further, lab experiments that compare piston temperatures to internal pump, or pump-based,  
827 temperatures (the latter using the empirically derived equations) found a 1-3K difference,  
828 prompting an additional equation that corrects for this temperature bias [Smit et al., 2014]. The  
829 resultant pump temperature corrections required for each case listed in Table 2.6.1 are:

830

831 Case 1: Equation 2.6.1

- 832 (a)  $T_{P_{case1}} = 7.43 - 0.393\text{Log}_{10}(P)$   $P \geq 40$  hPa  
833 (b)  $T_{P_{case1}} = 2.7 - 2.6\text{Log}_{10}(P)$   $6 < P < 40$  hPa  
834 (b)  $T_{P_{case1}} = 4.5$   $P \leq 6$  hPa

835

836 Case 2, 3: Equation 2.6.2

- 837 (a)  $T_{P_{case2,3}} = 20.6 - 6.7\text{Log}_{10}(P)$   $P > 70$  hPa  
838 (b)  $T_{P_{case2,3}} = 8.25$   $15 \leq P \leq 70$  hPa  
839 (c)  $T_{P_{case2,3}} = 3.25 - 4.25\text{Log}_{10}(P)$   $5 \leq P < 15$  hPa

840

841 Case 4: Equation 2.6.3

- 842 (a)  $T_{P_{case4}} = 6.4 - 2.14\text{Log}_{10}(P)$   $P > 40$  hPa  
843 (b)  $T_{P_{case4}} = 3.0$   $3 \leq P \leq 40$  hPa

844

845 Case 5: No adjustment, i.e.  $T_{P_{case5}}=0.0$

846  
847 The additional correction to account for differences between  $T_{\text{piston}}$  and the internal pump, or  
848 pump based, temperatures is described as:

849  
850 Equation 2.6.4 
$$T_{\text{piston-internal}} = 3.9 - 0.8\text{Log}_{10}(P)$$

851  
852 It is recognized by GRUAN that equations 2.6.1 to 2.6.4 were derived from small statistical  
853 samples (Equation 2.6.4 from a sample of only three ECC sondes in the JOSIE chamber  
854 experiments; Figure 9 from Smit et al. [2007]). The adjustment formulae for Cases 2 and 3 were  
855 derived from a sample size of eight, while only three sondes were used to generate the Case 4  
856 formula. Until GRUAN can conduct more detailed analyses of the biases related to different  
857 placements of the sonde thermistor, the uncertainties inherent in the small samples underlying  
858 equations 2.6.1 to 2.6.4 must be propagated through to uncertainties in the derived ozone partial  
859 pressures. Section 6.5 summarizes the pump temperature uncertainty parameters and equations  
860 and how these contribute to the ozone partial pressure uncertainty.

861  
862 The ASOPOS panel recommends that the final adjusted pump temperature,  $T_p$ , used to calculate  
863 the ozone partial pressure, should be defined as:

864  
865 Equation 2.6.5 
$$T_p = T_{\text{measured}} + T_{\text{Pcase}_i} + T_{\text{piston-internal}}$$

866  
867 where  $T_{\text{measured}}$  is the pump temperature recorded by the sonde,  $T_{\text{Pcase}_i}$  is the correction that  
868 depends on the case, and  $T_{\text{piston-internal}}$  is the additional correction defined by equation 2.6.4.  
869

## 870 2.7 Determining the partial ozone column above the top of flight

871 GRUAN's purpose for calculating total column ozone for each profile is to allow for  
872 comparisons against an independent spatially and temporally co-located total column ozone  
873 measurement to provide a means of validating the quality of the ozonesonde ozone profile. The  
874 standard technique for computing total column ozone from an ozonesonde measurement includes  
875 adding a climatological ozone partial column value above the balloon burst altitude. Most often,  
876 these partial columns are based on satellite and ozonesonde observations [McPeters et al, 1997,  
877 2007, 2012; Labow et al., 2015], though some sites have developed their own monthly  
878 climatologies e.g. based on microwave radiometer-derived ozone profiles. Comparisons of the  
879 integrated ozonesonde ozone profile plus the partial column above the top of flight can then be  
880 made with ground-based and satellite measurements of total column ozone (e.g. Dobson  
881 spectrophotometer, Brewer spectrometer, OMI, GOME-2).

882  
883 When integrating ozonesonde profiles within a GRUAN ozonesonde programme, that integration  
884 shall be truncated at 7 hPa since the ozone profile above 7 hPa has higher uncertainty due to the  
885 degradation of the pump efficiency (Section 2.5) and evaporative effects on the sensing solution  
886 at very low pressures [Bryan Johnson/NOAA, private communication]. It is preferable that  
887 GRUAN sites derive their own monthly climatologies of ozone partial columns above the top of  
888 the flight since these will be more relevant than the zonal mean climatologies provided by  
889 McPeters et al. [2012]. It is important that these climatologies include uncertainties so that these  
890 can be propagated through to the derived ozonesonde total column ozone uncertainty. Until site-

891 specific climatologies are available, the McPeters et al. climatologies may be used to derive the  
892 ozone partial column above the burst pressure. Where the balloon bursts at pressures higher than  
893 the McPeters et al. [2012] pressure limit of 32 hPa a total column ozone value cannot be derived  
894 and the flight total column ozone value should be recorded as a null value.. It is recognized that  
895 there may be gaps in the profile measurements due to intermittent telemetry. Profiles with large  
896 data gaps shall be identified and evaluated on a case-by-case basis and the flight total column  
897 ozone value and, importantly, its uncertainty, calculated according. The GRUAN ozonesonde  
898 data product shall include the following ozone column-related metadata:

- 899 • The integrated ozone column amount (in DU) up to 7 hPa or balloon burst, whichever is  
900 lower.
- 901 • The pressure level at the top of the integration [hPa].
- 902 • The ozone partial column (in DU) above burst pressure either from the McPeters et al.  
903 [2012] climatology or from the site-specific climatology.
- 904 • If available, co-located ground-based or space-based measurements of total column  
905 ozone shall be included.

906 GRUAN encourages sites to include any ancillary measurements of surface and column ozone  
907 measurements in the metadata submitted to the centralized GRUAN ozonesonde data processing  
908 facility. Redundancy in ozone measurement systems provides a powerful tool for validating and  
909 evaluating the ozone measurements in any given time series.

910

## 911 2.8 Dependence on the radiosonde

912 Radiosonde pressure and temperature measurements are used to calculate the geopotential  
913 heights. Thus, radiosonde measurement errors will cause the measured ozone to be assigned  
914 incorrect altitudes and pressures. As with ozonesondes, there are a number of radiosonde  
915 manufacturers whose instruments have changed in model, material, and algorithm since the  
916 1970's. There are measurable differences between manufacturers, i.e. Vaisala vs iMET, and  
917 between models, i.e. Vaisala RS-80 vs RS-92, that impact the ozonesonde measurement,  
918 particularly at low pressures [Smit et al., 2014; and references therein]. GRUAN shall document  
919 radiosonde manufacturer, model and type of interface so that appropriate calibrations and  
920 corrections to the pressure and temperature, as well as RH, can be made in the pre- and post-  
921 processing calculations of the geopotential height.

922

923

### 924 GRUAN procedure protocol

925

- 926 • Calibration of the radiosonde surface pressure, temperature, RH and determination of any  
927 offset between geopotential and GPS height measurements, if and when available, shall  
928 follow the processing guidelines dictated by the GRUAN Radiosonde Technical  
929 Document (X.X.X).
- 930 • Handling biases in the geopotential height calculation in the absence of GPS  
931 measurements shall be the responsibility of the Radiosonde WG-GRUAN, task team, and  
932 Lead Centre.
- 933 • Radiosonde/Ozonesonde offsets in height and pressure, if any, shall be documented and  
934 geopotential heights shall be recalculated by the Lead Centre GOASS (refer to Section  
935 3.7).

- 936 • Quantifying the contribution of the radiosonde uncertainty to the ozone measurements, if  
937 any, shall be the responsibility of the Radiosonde WG-GRUAN, task team, and Lead  
938 Centre.  
939

## 940 **2.9 Conversion efficiency**

941 One of the terms in the ozone uncertainty calculation is the contribution of the uncertainty in the  
942 conversion efficiency. The conversion efficiency refers to the stoichiometric factor of 1:1  
943 assumed in the  $I_2:O_3$  relationship. Interferences with this one-to-one relationship can arise from  
944 the buffering of the solution [Johnson et al. 2002; Vömel and Diaz, 2010]. The cathode solution  
945 contains a buffer of sodium-hydrogen phosphate to maintain the solution concentration and a  
946 neutral pH of 7.0 during flight. GRUAN shall follow a half buffered cathode solution for ENSCI  
947 sensors and a full buffer for SPC, as recommended by WMO/ASOPOS [Smit et al., 2012; 2014].  
948 Johnson et al. [2002] performed stoichiometric sensitivity and pH tests and measured excess  
949 ozone at low pressures due to the buffering effect. This would yield a  $I_2:O_3$  relationship larger  
950 than unity. This offset in the stoichiometry has been documented by others (Smit et al., 2014,  
951 section 3.2.2 and references therein; Johnson et al, 2002, section 2.1 and references therein). In  
952 the ozone partial pressure equation, Equation 1, the conversion efficiency is assumed to be unity  
953 and is therefore excluded from the equation. However, the uncertainty of this unity assumption  
954 can be a significant contributor to the ozone uncertainty estimates and is addressed in Section  
955 6.6.

### 956 3 GRUAN OZONESONDE PROGRAMMES

957 The GRUAN Guide (herein referred to as GCOS-171) states that the primary objective of  
958 GRUAN is to provide reference measurements for a range of upper-air climate variables.  
959 Reference quality observations are based on key concepts in metrology, in particular traceability.  
960 Metrological traceability is the process whereby a measurement and its uncertainty, can be  
961 related to a reference through a documented, unbroken chain of calibrations, each of which  
962 contributes to the measurement error.

963  
964 To provide the best measurements of ozone and its uncertainty, a detailed understanding of the  
965 instrumentation, standard operating procedures (SOPs), and data processing is required. To lend  
966 confidence in the long-term stability of the data records for a single GRUAN Ozonesonde  
967 Programme and the entire network as a whole, the instrumentation, standard operating  
968 procedures, and data processing must produce datasets that are homogenized across the entire  
969 network.

970  
971 For this reason, GRUAN ozonesonde certification applies to the overall infrastructure underlying  
972 the ozonesonde measurement and the subsequent production of a final GRUAN ozonesonde  
973 reference product. This infrastructure is defined in the present report as a GRUAN Ozonesonde  
974 Programme, and includes

- 975 1. the SOPs that condition and calibrate each ozonesonde instrument prior to launch,
- 976 2. the mandatory collection of metadata used to characterize the singular features of each  
977 unique ozonesonde instrument,
- 978 3. the acquisition of the raw data and metadata to the RSLaunchClient utility for central  
979 processing,
- 980 4. the steps involved for create a final homogenized GRUAN ozonesonde product,
- 981 5. the handling of storage and dissemination of all pertinent levels of ozonesonde  
982 measurements.

983  
984 In order to be GRUAN-certified each GRUAN Ozonesonde Programme must include the  
985 following three mandatory components:

- 986 1. The GRUAN Ozonesonde Instrumentation and Measurement Report (GOIMP): A  
987 dynamic document submitted to the GRUAN Lead Centre, via email, by the GRUAN  
988 ozonesonde programme representative describing their measurement program and  
989 capabilities, as well as documentation on the history of its ozonesonde data record, if any.  
990 The GOIMP shall include all aspects of the programme such as instrumentation  
991 inventory, SOPs, measurement schedule, and up-to-date data acquisition and archiving  
992 status. Further details of what should be included in the report are addressed in Section  
993 3.2.
- 994 2. Proof of the ability to provide all essential metadata and raw data to the RSLaunchClient  
995 utility: An interactive JavaScript tool designed to compile all metadata associated with  
996 each ozonesonde instrument launched (i.e. those measurements collected by the ground  
997 station data acquisition system per launch). The essential metadata is described in Section  
998 3.6 and is upload together with the raw data by the RSLaunchClient at a designated

999 GRUAN ozonesonde data handling centre for processing by the GRUAN Ozonesonde  
1000 Analysis Software System (GOASS). All metadata uploaded by RSLaunchClient shall be  
1001 consistent with the latest version of the GRUAN check list (found in Appendix A-1 and  
1002 A-2 for refurbished sondes).

1003 3. The GRUAN Ozonesonde Analysis Software System (GOASS): A centralized data  
1004 processing software collecting and analyzing in a standardized manner the raw-data of all  
1005 certified GRUAN ozonesonde instruments sent out through the RSLaunchClient utility.  
1006 Before processing the raw data, the GOASS reconciles the metadata received from the  
1007 RSLaunchClient with those contained in the GOIMP. Any inconsistency is immediately  
1008 reported, thus providing a near-real-time check of the measurement traceability and  
1009 stability, as well as a quick identification of change. The output of the GOASS consists of  
1010 certified GRUAN ozonesonde products of various levels designed to be used by different  
1011 communities for different science applications. Individual GRUAN Ozonesonde  
1012 Programmes will be audited, as well as annually reviewed in compliance with the  
1013 requirements and recommendations of GCOS-171 and this present document. GRUAN  
1014 Ozonesonde Programmes not in compliance all three of the mandatory components listed  
1015 above may lose their GRUAN certification.

1016 **3.1 Site assessment and certification considerations for GRUAN Ozonesonde**  
1017 **Programmes**

1018 Ozonesonde sites seeking to become a GRUAN Ozonesonde Programme will be subjected to the  
1019 same assessment and certification process as all other sites in the network. This section provides  
1020 pragmatic criteria for assessing and certifying existing and new sites. Ozonesonde sites will  
1021 follow the specific requirements regarding site assessment and certification under Section 5.1 of  
1022 GCOS-171.

1023  
1024 GRUAN recognizes that sites will vary in infrastructure and financial support. In order to be  
1025 compliant with the mandatory operating protocols defined in Sect. 5.3 of GCOS-171, each  
1026 GRUAN Ozonesonde Programme should do the following:

- 1027  
1028 1. Provide reference quality observations, i.e., observations characterized by a traceable  
1029 calibration, a comprehensive uncertainty analysis, a readily accessible documentation, a  
1030 validation through inter-comparison campaigns, and complete metadata availability.
- 1031 2. Provide access to raw data and assure long-term storage of the raw data, as well as  
1032 metadata, either at the site, at another GRUAN facility, or at another internationally  
1033 accessible archive in accordance with the GRUAN Data Policy document (referred to in  
1034 Section 8.2 GCOS-171).
- 1035 3. Provide complete metadata for each measurement as defined in Section 3.6 of this  
1036 document.
- 1037 4. If available, and certainly encouraged, provide redundant reference observations of ozone  
1038 from co-located ground-based instruments for independent evaluation and validation  
1039 (refer to Sections 7.7 and 8.3 on parallel observations and validation, respectively).
- 1040 5. Provide annual reports summarizing the ozonesonde operations at the site, including  
1041 changes in instrumentation, how those changes were managed, and any improvements  
1042 made.
- 1043 6. Conduct the ozonesonde programme with an operational philosophy of continually  
1044 striving to improve measurement accuracy (e.g., by working with other GRUAN  
1045 Ozonesonde Programmes, or participating in field and laboratory experiments).
- 1046 7. Manage change proactively as defined in Section 7 of this document.
- 1047 8. Actively communicate with the GRUAN Lead Centre, WG-GRUAN and GRUAN Task  
1048 Team for Sonde (TTS) through attendance at meetings and emails.

1049  
1050 Specifically, GRUAN ozonesonde certification shall be assessed based on the follow criteria:

- 1051  
1052 1. The content and completeness of the GOIMP each ozonesonde candidate site is required  
1053 to file at the designated GRUAN Lead Centre (refer to Section 3.2).
- 1054 2. The level to which the ozonesonde candidate site conforms to GRUAN prescribed SOPs  
1055 consistent with WMO GAW Report 201 to guarantee homogeneity of quality across the  
1056 network. Determining whether the SOPs of an existing site meet the prescribed operating  
1057 protocols will be done objectively against the standards outlined in Section 3.5.
  - 1058 i. Sites that do not meet the WMO operating procedure standards can choose to adopt  
1059 the prescribed SOPs in order to qualify to become a GRUAN site.
  - 1060 ii. New sites shall be expected to adopt the GRUAN prescribed SOPs.

- 1061           iii. Sites that launch refurbished ECC-sensors should follow the NOAA re-conditioning  
1062           SOPs in Appendix A-2 or manufacturer SOPs (refer to Section 4.5).
- 1063           3. The level to which the ozonesonde candidate site conforms to the GRUAN prescribed  
1064           conditioning and pre-flight check list whose metadata will be collected by the  
1065           RSLaunchClient. Metadata requirements from the check list are addressed in Section 3.6.
- 1066           4. The schedule frequency where a minimum of twice monthly launches spaced bi-weekly  
1067           is required. This is addressed in Section 5.2. A **fully** operating GRUAN Ozonesonde  
1068           Programme shall perform weekly launches. Weight shall be given to the added value  
1069           each candidate site brings to the network (see Section 3.2.1 below).
- 1070

### 1071           **3.2           GRUAN Ozonesonde Programme assessment and certification** 1072           **process**

1073

1074           A schematic of the site assessment and certification process is provided in Figure 2 of GCOS-  
1075           171.

1076

1077           Once a site has been identified for possible inclusion in GRUAN, through either of the routes  
1078           shown in Figure 2 of GCOS-171, the following sequence of events will be used to assess the site  
1079           for potential GRUAN certification:

1080

- 1081           1. The candidate site will be given the GRUAN manual (GCOS-171) and this ozonesonde  
1082           technical document, as well as documentation describing data submission protocols and  
1083           the procedures that must be followed when data are submitted to the internal GRUAN  
1084           archives via the RSLaunchClient (addressed in Section 3.6).
- 1085
- 1086           2. The response from the candidate site shall be given in the form of the GOIMP submitted  
1087           to the designated GRUAN Lead centre and should include:
- 1088
- 1089           1. If it is an established GRUAN site that proposes to add an ozonesonde measurements  
1090           programme or a new GRUAN site that will include an ozonesonde measurement  
1091           programme.
- 1092           2. A complete description of how the ozonesonde measurement programme will be  
1093           conducted. Such information would include launch frequency and scheduling,  
1094           detailed SOPs, a copy of the check list and metadata inventory, and data storage  
1095           policies. This information must be sufficient to establish the ability of the site to meet  
1096           the mandatory operating protocols outlined in Sections 3.5 – 3.7.
- 1097           3. Include any cooperative agreements with other sites and institutions already in the  
1098           network. This is highly desirable to ensure that expertise is disseminated to similar  
1099           measurement programmes in operation at other sites.
- 1100           4. The management structure of the site and a general description of the manner in  
1101           which the site is operated. This would include a description of current and expected  
1102           future funding levels for on-going operation of the site.

- 1103 5. A description of which data centres the measurements have previously been  
1104 submitted to and are currently being submitted to.
- 1105 6. A description of how past ozonesonde measurements from the site have been  
1106 processed. This will be used to assess whether the time series to date meet the  
1107 standards for a GRUAN reference measurement. Particularly important in this regard  
1108 will be detailed documentation around how changes in SOPs over the history of the  
1109 measurement programmes have been managed to derive a homogeneous time series  
1110 of measurements.
- 1111 7. A description of past metadata data records and storage. This will be used to assess  
1112 whether the time series to date meet the traceability standards for a GRUAN  
1113 reference measurement.
- 1114 8. A list of the ozonesonde experts employed at the site who would likely participate in  
1115 the analyses of the data collected within GRUAN. This may include mention of  
1116 experts at partnering scientific organizations.
- 1117 3. There is likely to be some iteration between the Lead Centre and the candidate site to  
1118 confirm specific details, fill in information gaps, and finalize the documentation from the  
1119 candidate site.
- 1120 4. Based on the documentation received from the candidate site, the Lead Centre will then  
1121 write a short recommendation. This, together with the documentation from the candidate  
1122 site, will then be submitted to the WG-GRUAN who will evaluate the proposal within 6  
1123 calendar months against the requirements listed in Sections 3.5, 3.6, and 4. One or more  
1124 visits to the site by members of the WG and/or Lead Centre within this 6-month period  
1125 may be required to obtain specific additional information about the measurement  
1126 programmes slated for inclusion in GRUAN at that site. If accepted, these measurement  
1127 programmes will then be included in the GRUAN certification for the site.
- 1128 5. Regardless of the outcome, the WG-GRUAN and Lead Centre will provide written  
1129 constructive feedback to the candidate site outlining strengths and weaknesses of their  
1130 programme for GRUAN purposes and suggestions as to future improvements for  
1131 GRUAN operational purposes. This feedback is non-binding but rather intended to  
1132 provide useful guidance and support to site capability development and retention of  
1133 current capabilities.
- 1134 6. Annual reports shall summarize GRUAN operations at the site identifying any changes in  
1135 ECC or radiosonde instrumentation, scheduling, procedures, equipment, and  
1136 improvements. The intent of the annual report is to ensure that SOPs developed for the  
1137 network have been adhered to, and to identify changes that may require additional  
1138 reprocessing that is not already taken into account or require re-assessment of GRUAN  
1139 certification. These reports will be presented at annual GRUAN meetings.

### 1140 **3.2.1 Criteria for assessing added value**

1141

1142 The GRUAN Ozonesonde Programme assessment and certification process follows closely the  
1143 more general GRUAN site certification process described in Section 5.5 of the GCOS-171. Once

1144 a site has committed to operating a set of measurement programmes under the protocols defined  
1145 in Section 5.3 of GCOS-171, the added value that an ozonesonde site brings to the GRUAN  
1146 network will be assessed according to:

- 1147 • The extent to which the ozonesonde site can fulfill the measurement programme expected  
1148 of a fully equipped GRUAN site (Section 3.1). Achieving all of the measurement  
1149 programme requirements is not mandatory for the inclusion of a site in GRUAN.  
1150 However, the extent to which a site can meet these requirements will determine, in part,  
1151 the additional value that that site brings to the network. For example, ozonesonde sites  
1152 located in a large region of the globe containing no other GRUAN Ozonesonde  
1153 Programmes and making the minimum required bi-weekly launches will be assessed as  
1154 adding as much value to the network as a site making weekly reference quality  
1155 measurements but located very close to another GRUAN ozonesonde site. These high  
1156 priority measurement programmes will be refined as the research which forms their basis  
1157 progresses. This documentation will be updated to reflect scientific requirements.
- 1158 • The extent to which the ozonesonde site provides profiles measurements of ozone in  
1159 regions of atmospheric phenomena which were not previously sampled. In this case, the  
1160 added value will depend on the locations and capabilities of the sites already participating  
1161 in the network.
- 1162 • The extent to which the ozonesonde site brings unique observational and/or analysis  
1163 capabilities aligned with GRUAN scientific objectives to the network as a whole and the  
1164 likelihood of being able to propagate those capabilities across other sites in the network.
- 1165 • The extent to which the ozonesonde site is prepared to forgo locally established operating  
1166 procedures and adhere to the SOPs established by the Lead Centre and adopted by the  
1167 majority of the sites already in the network. Unwillingness or inability to do this would  
1168 count against a site in the assessment of the added value it would bring to the network.
- 1169 • The availability of historical measurements that conform to the GRUAN standard. All  
1170 else being equal, a candidate site that extends an existing multi-decadal time series of  
1171 reference quality measurements will be assessed as adding more value to the network  
1172 than a site that would initiate the same measurement programme starting at the present.  
1173 Detailed documentation in the GOIMP would be required describing how changes in  
1174 SOPs, instruments, calibration procedures, data processing algorithms and operators over  
1175 the history of the measurement programmes have been managed to ensure that the  
1176 historical measurements are reference quality. Where historical reference quality  
1177 measurements are available, consideration will be given by the WG-GRUAN and Lead  
1178 Centre to providing these as GRUAN data through the GRUAN data archives.
- 1179 • The extent to which the ozonesonde site can commit to a multi-decade programme of  
1180 measurements. While it is recognized that a multi-decade programme of measurements  
1181 cannot be guaranteed, a statement of intent with documented support (e.g. from the host  
1182 institution or relevant funding agency) will add to the assessment of the value that the site  
1183 brings to the network.
- 1184 • The extent to which the ozonesonde site can provide redundant observations of the  
1185 priority 1 and ECVs or can conduct periodic inter-comparisons and laboratory studies.

- 1186 • The extent to which a site is capable of measuring other ECVs identified in GCOS-112 as  
1187 being desired quantities.
- 1188 • The level of institutional support for the site and commitment to maintaining long-term  
1189 reference quality measurement programmes. If, in addition, a site can demonstrate that it  
1190 is actively pursuing resources to enhance its capability, such as the addition of new  
1191 measurement programmes, this would also enhance the added value the site would bring  
1192 to the network. It is also desirable that there is full host institution commitment to  
1193 GRUAN-related activities and that this commitment is not dependent on a single  
1194 individual.
- 1195 • The level of institutional support for the site (and any partner institutions) to undertake  
1196 fundamental scientific research of the measurements from the site and other GRUAN  
1197 sites. Because GRUAN includes aspects of both operational and research networks, a  
1198 strong and ongoing science programme is required to ensure that GRUAN fulfills its role  
1199 as a research network.
- 1200 • The degree of historical or planned cooperation with other sites both within and outside  
1201 the GRUAN network including other GRUAN-relevant networks e.g. NDACC,  
1202 SHADOZ, GAW, and WOUDC.

1203 Such assessments of added value shall rely on the expert judgement of the WG-GRUAN and  
1204 Lead Centre, recognize the heterogeneity of the sites within the network, and facilitate a practical  
1205 approach to expansion of the network following the 2009-2013 implementation phase for  
1206 GRUAN (GCOS-134) and its amendments.

1207 Determining optimal locations for GRUAN sites as part of added-value assessment to ensure that  
1208 the needs of the user community are met shall consider the following:

- 1209 1. Covers a major climate region.
- 1210 2. Covers a region of large atmospheric modes, e.g. ENSO, SAM, QBO
- 1211 3. Environment, e.g. tropics, mountainous, desert, island
- 1212 4. Spatial co-location with other Ozonesonde Programmes

### 1214 **3.3 GRUAN Ozonesonde Training Programme**

1215 Operational uncertainty includes uncertainties related to instrument set-up and operation. To  
1216 reduce operational uncertainty, and in line with Section 1.4 of GCOS-171, the Lead Centre and  
1217 WG-GRUAN shall identify Ozonesonde Programmes where instrument operators need training  
1218 on GRUAN ozonesonde SOPs, and shall organize cost-efficient training courses for those  
1219 operators at appropriate locations to encourage uniformity of ozonesonde instrument operation  
1220 between sites. At least one staff member of a GRUAN Ozonesonde Programme should be in  
1221 attendance to an initial training session in which the GRUAN-specific ozonesonde best  
1222 measurement practices and the use of RSLaunchClient are taught. The GRUAN Ozonesonde  
1223 Programme representative shall be one of the trained staff.

1224 In addition to training at the time of certification, training is required for any new measurement  
1225 scientist joining the ozonesonde programme team. Though training may be done through other

1226 existing members of staff, it is strongly recommended that a GRUAN training session be  
1227 provided at a GRUAN site where optimal standard operating procedures are kept up-to-date.

1228 If WG members deem that a potential candidate requires training, or an existing GRUAN  
1229 Ozonesonde Programme requires re-training, GRUAN will try to partner the site organization  
1230 with an ozonesonde expert who can do a site visit for training or re-training. The Lead Centre  
1231 require that at least one member of the WG-GRUAN is an ozonesonde expert. An ozonesonde  
1232 expert includes operators of a GRUAN Ozonesonde Programme, members of ASOPOS, or other  
1233 ozonesonde experts that have participated in JOSIE studies and ozonesonde inter-comparison  
1234 field campaigns. Thus, although not required, re-training may be done by an ozonesonde expert  
1235 within the WG-GRUAN.

1236 For those GRUAN Ozonesonde Programmes already partnered with ozonesonde launch experts,  
1237 training and maintaining up-to-date practices shall be coordinated between the two partners.  
1238 Sites that require re-training will be determined by these means:

- 1239 • A GRUAN site makes a formal written request for re-training to the Lead Centre.
- 1240 • When the WG-GRUAN concludes that upon reviewing a sites annual report that re-  
1241 training is necessary to guarantee consistency of quality.
- 1242 • An audit, addressed in Section 3.10, reveals deficiencies in the operating procedures that  
1243 necessitate re-training to maintain GRUAN certification.

### 1244 **3.4 GRUAN Ozonesonde Programme data management**

1245 General considerations shall be drawn from Section 8 of GCOS-171.

#### 1246 **3.4.1 Overview of the data flow**

1247 Refer to Figure 3 of GCOS-171 which shows a schematic representation of the flow of data in  
1248 GRUAN to the user community.

1249 GRUAN data levels *relevant to ozonesondes* are based on the GRUAN Data Management  
1250 Manual:

- 1252 • Level 0 (L0): Original primary raw data (PRD). This is the ‘rawest’ form of data  
1253 available before any processing has been applied, i.e., the raw data slices acquired by the  
1254 data acquisition electronics
- 1255 • Level 1 (L1): Converted raw data (CRD). These data are stored in a common well-  
1256 described file format intended for long-term storage. They are pre-processed raw data and  
1257 might already represent parameters to be used in end-user’s application
- 1258 • Level 2 (L2): Standard GRUAN product data (SGPD) resulting from all processing steps  
1259 associated with a single instrument.

1260  
1261 Measurements and metadata are bound together in each of these data levels. PRD are ingested  
1262 from all GRUAN sites into the internal GRUAN data archive hosted at the Lead Centre. Direct  
1263 exchange of PRD between sites is discouraged since this circumvents the data versioning  
1264 protocols and reduction of the raw data to a common CRD file format. Similarly, direct exchange  
1265 of CRD between sites is discouraged since this circumvents network wide application of

1266 corrections, re-processing, and homogenization techniques applied to convert CRD to SGDP that  
1267 would be implemented at the Lead Centres' data processing facility.

1268

### 1269 **From PRD data submission to processing, storing and dissemination of SGPD**

1270

1271 1. Level 0 ozonesonde raw data (PRD) and metadata, listed in Section 3.6, shall be collected  
1272 by the RSLaunchClient utility.

1273 2. A complete list of the essential and desirable PRD is found in Table 3.1 of this section.

1274 3. A complete list of the essential and desirable metadata is found in Table 3.4 of this  
1275 section.

1276 4. Each GRUAN site is responsible for storing the PRD and associated metadata in its  
1277 original format and in digital format.

1278 5. The PRD shall be saved as Level 1 converted raw data (CRD) via the RSLaunchClient.

1279 6. Processing of the ozonesonde raw data will be held in the designated GRUAN internal  
1280 data archive at the Lead Centre.

1281 7. The Lead Centre GOASS will be responsible for using the CRD and essential metadata to  
1282 create the final standard ozone products (SGPD), as outlined in Section 3.7.

1283 8. A complete list of SGPD are found in Table 3.2 of this section.

1284 9. A designated GRUAN Lead Centre storage facility shall be responsible for archiving and  
1285 maintaining the ozonesonde metadata, CRD, and SGPD for all Ozonesonde Programmes.

1286 10. The SGPD, including their metadata and documentation, will be provided to the user  
1287 community through the external GRUAN data archive hosted at NCEI.

1288

1289 Processing of the CRD, held in the GRUAN internal data archive, to produce SGPD will occur at  
1290 the designated Lead Centre central processing facility. This processing should include applying  
1291 the necessary corrections, and uncertainty estimates in a consistent and traceable manner across  
1292 identical instruments from other Ozonesonde Programmes. The SGPD, including their metadata  
1293 and documentation, are provided to the user community through the external GRUAN data  
1294 archive currently hosted at NCEI. A performance monitoring process (see Section 9 of GCOS-  
1295 171), implemented at the Lead Centre, will provide feedback on performance to individual sites.

1296

### 1297 **3.4.2 GRUAN data policy**

1298 Since GRUAN is co-sponsored by WMO, GRUAN ozonesonde data dissemination and use shall  
1299 comply with WMO Resolution 40 (Cg-XII) which calls for free and unrestricted international  
1300 exchange of data. Refer to Section 8.2 of GCOS-171 for further details on the data dissemination  
1301 and exchange policy.

### 1302 **3.4.3 Collation of Metadata**

1303 Essential and desirable metadata are listed in Section 3.6.1. Metadata will be submitted via the  
1304 RSLaunchClient utility and archived at the designated GRUAN Lead Centre and NCEI.

1305 “Desirable” metadata defined in Section 3.6.1 are not required and the RSLaunchClient will not  
1306 reject profiles if these desirable variables are excluded.

1307

1308 Metadata should not preclude information derived from historical documents such as observing  
1309 practices manuals, site inspection reports, government policies, resource and funding  
1310 programmes.

1311  
1312 Management and maintenance of metadata requires the investment of resources. Present day  
1313 technology for database warehousing of digitized metadata has the added benefit that metadata  
1314 can be accessed, linked to measurements, and easily transferred. To facilitate metadata collation,  
1315 the RSLaunchClient utility will be responsible for ingesting as much metadata as possible to be  
1316 saved and stored at a designated GRUAN archive. Ozonesonde Programmes are required to keep  
1317 original copies of their metadata at their own storage facility, as secondary storage back-up.

1318  
1319 Metadata documents related to historical operations at GRUAN sites and to historical data  
1320 archives should be inventoried and properly conserved until such time as their information  
1321 content can be transferred to a medium which supports multiple users' access and conforms to  
1322 GRUAN reference measurement guidelines.

1323  
1324 Metadata needs to have the same level of commitment as observed data. Incomplete, outdated, or  
1325 inaccurate metadata can be as detrimental, indeed in some cases worse, than no metadata at all.

1326 Regular reviews of metadata content for confirmation and accuracy should be part of regular  
1327 GRUAN operations. Support to investigate new metadata sources, information management  
1328 technologies and information sharing capabilities should be on-going in an effort to make  
1329 accessible and preserve the historical investment in the data collected.

1330

1331

### 1332 3.4.4 Ozonesonde Data Products

#### 1333 The Ozonesonde Primary Raw Data (PRD)

1334

1335 Each ozonesonde launched generates an array of measurements captured by the ground station  
1336 data acquisition system. The PRD generally measures, but is not limited in measuring, the  
1337 following variables listed in Table 3.1. The essential data variables listed are the basic  
1338 fundamental data variables that are to be collected by the RSLaunchClient. The RSLaunchClient  
1339 will collect and manage uploaded ozonesonde PRD to the designated GRUAN Lead Centre. All  
1340 the PRD shall be saved to a Level 1 converted raw data (CRD) file for archiving at the  
1341 designated GRUAN Lead Centre storage facility and processing shall be done by the GOASS  
1342 addressed in Section 3.7 to create the SGDP. Desirable PRD (in blue) is not required input to the  
1343 RSLaunchClient and profile data will not reject if these desirable variables are excluded.  
1344

1345 **Table 3.1 Essential and Desirable Ozonesonde Primary Raw Data (PRD) variables**

1346

1347 16. Time [min]

1348 17. Time GMT [hh:mm:ss]

1349 18. Pressure [hPa]

1350 19. Geopotential height [gpm]

1351 20. Temperature [K]

1352 21. Relative Humidity [%]

1353 22. Ozone Partial Pressure [mPa]

1354 23. Ozone Mixing Ratio per volume [ppm]

1355 24. Horizontal Wind Direction [decimal degrees] (range: 0:360)

1356 25. Horizontal Wind Speed [m/s]

1357 26. GPS Geometric Height [m]

1358 27. GPS Longitude [decimal degrees] (range: -180:+180)

1359 28. GPS Latitude [decimal degrees]

1360 29. GPS Satellites

1361 30. GPS Time GMT [hh:mm:ss]

1362 31. GPS Pressure [hPa]

1363 32. Internal Temperature [K] (box or pump)

1364 33. Ozone Current [ $\mu$ A]

1365 34. Battery Voltage [V]

1366 35. Pump Current [ $\mu$ A]

1367 36. Rise Rate [m/s]

1368

#### 1369 The Ozonesonde Standard GRUAN Data Product (SGDP)

1370

1371 Each PRD should be archived at the same vertical and temporal resolution. Thus, each  
1372 ozonesonde profile shall archive SDPG at the same vertical and temporal resolution. The  
1373 GOASS shall use the PRD, in conjunction with the metadata also collected from the  
1374 RSLaunchClient, to generate the ozonesonde SGPD. Section 3.7 goes through the GOASS steps  
1375 required to generate the ozonesonde SGPD from the CRD. The family of ozonesonde SGPD are

1376 listed in Table 3.2. Apart from the uncertainty estimates, it is not mandatory for all variables  
 1377 under the ozonesonde SGDP family to be measured. For example, heritage ozonesonde  
 1378 measurements used radiosondes that did not have the means or capability of acquiring GPS  
 1379 information.

1418

1419

1420

1421

1. Time [min]
2. Radiosonde Pressure [hPa]
3. Radiosonde Pressure Offset [hPa]
4. Geopotential height [gpm]
5. Radiosonde Temperature [K]
6. Radiosonde Temperature Offset [K]
7. Radiosonde Relative Humidity [%]
8. Radiosonde RH offset [%]
9. Ozone Partial Pressure [mPa] using Equation 2.6.5
10. Ozone Partial Pressure uncertainty [%] using Equation 6.5.2
11. Ozone Partial Pressure [mPa] using Equation 2.6.6
12. Ozone Partial Pressure uncertainty [%] using Equation 6.5.1
13. Ozone Mixing Ratio per volume [ppm] using (9) of this list.
14. Ozone Mixing Ratio per volume [ppm] using (11) of this list.
15. Radiosonde Horizontal Wind Direction [decimal degrees] (range: 0:360)
16. Radiosonde Horizontal Wind Speed [m/s]
17. Radiosonde GPS Geometric Height [m]
18. Radiosonde GPS Longitude [decimal degrees] (range: -180:+180)
19. Radiosonde GPS Latitude [decimal degrees]
20. Internal Temperature [K] (box or pump)
21. Ozone Current [ $\mu$ A]
22. Ozone Current and background contribution (Section 6.2)
23. Ozonesonde Pump Flow rate,  $\Phi$  (Section 6.3).
24. Ozonesonde Pump Correction Factor,  $\Psi$ , (Section 6.4).
25. Ozonesonde Pump Temperature,  $T_p$  (Section 6.5).
26. Ozonesonde Conversion efficiency,  $\eta$  (Section 6.6).
27. Radiosonde Pressure and Temperature offset uncertainty [defined and addressed in the GRUAN Radiosonde Technical Report (X.X.X)]
28. Total Column Ozonesonde (TCO) [DU]
29. Pressure above which the TCO is calculated [hPa]
30. Partial column ozone above (29) [DU]

As seen from Table 3.2, uncertainty estimates shall form part of the ozonesonde SGDP collective. The Lead Centre GOASS shall be responsible for calculating these estimates addressed in detail in Section 6. The measurement uncertainty describes the current best knowledge of instrument performance under the conditions encountered during an observation and therefore merits its own separate listing in Table 3.3 below.

**Table 3.3 Uncertainty variables as part of the ozonesonde SGPD.**

- 1422 1. Ozone partial pressure uncertainty (Section 6.1).  
1423 2. Ozone Current and background contribution (Section 6.2)  
1424 3. Pump Flow rate,  $\Phi$  (Section 6.3).  
1425 4. Pump Correction Factor,  $\Psi$ , (Section 6.4).  
1426 5. Pump Temperature,  $T_p$  (Section 6.5).  
1427 6. Conversion efficiency,  $\eta$  (Section 6.6).  
1428 7. Radiosonde Pressure and Temperature uncertainty. These values will be calculated  
1429 according to the GRUAN Radiosonde Technical Report (X.X.X)  
1430  
1431  
1432

### 1433 **3.4.5 File naming convention**

1434 The filename convention described here is taken from Section 2.1 of the Manual for the Data  
1435 Management in GRUAN [GRUAN-TD-1 DRAFT v0.3v0.3 ( 2010-132010-07-13)] and will  
1436 apply for metadata XML files and for the CRD and SGPD data files in the designated GRUAN  
1437 Lead Centres file archive. The obligatory parts of the file names should be:

- 1438  
1439 • Unique Station Identifier → GAW ID and station location name, i.e.  
1440 NRB\_Nairobi\_Kenya  
1441 • Data level → number  
1442 • Data product level → CRD or SGPD (not used for metadata file naming)  
1443 • Version of data product → number  
1444 • Date / Time → in universal standard time (UTC)  
1445 • Date / Time of the creation of CRD and SGPD files  
1446 • Identification of the specific instrument → 'ECCSonde'  
1447 • Identification of central tracer → 'Ozone'

### 1448 **3.4.6 Data format**

- 1449 • Metadata will be provided to the end-user in XML format.  
1450 • CRD and SGPD will be stored in CSV ASCII format. SGPD will be provided to the  
1451 NCEI in that format. ASCII format is an accepted standard output used by the leading  
1452 ozonesonde archiving centers (SHADOZ, NDACC, and WOUDC).

### 1453 **3.4.7 Data dissemination**

- 1454  
1455 • Users of GRUAN data shall have access not only to the measurements and their  
1456 uncertainties, but also to the metadata information which includes instrument  
1457 specifications, operating procedures, data algorithms used, and when changes to any of  
1458 these occurred through the complete time period of the data set.  
1459 • Users shall have access to previous versions of the ozonesonde SGDP.

### 1460 **3.4.8 Data archiving**

1461

- 1462 • The ozonesonde metadata, CRD and SGPD are expected to be stored at the nominated  
1463 GRUAN central data processing facility Lead Centre.
- 1464 • A designated GRUAN storage facility should be established. This would:
  - 1465 ◦ Allow the Lead Centre to maintain statistics on data usage. This would be useful  
1466 when applying for funding to support GRUAN operations.
  - 1467 ◦ Allow users of data to be informed if and when newer versions of the data become  
1468 available.
  - 1469 ◦ Facilitate reporting of potential errors, flags, and anomalies in the data by end-users.
- 1470 • GRUAN sites shall be responsible for storing their PRD.
- 1471 • The metadata and SGPD shall be made available at the NCEI.
- 1472 • Ozonesonde data dissemination shall comply with the data policy guidelines in Section  
1473 8.2 of GCOS-171.
- 1474 • It is important that the GRUAN archive includes all previous versions of any given data  
1475 set so that analyses using previous versions of data can be repeated if required.  
1476

#### 1477 3.4.9 Data gaps

1478 GRUAN recognizes that there may be gaps in the profile measurements due to telemetry  
1479 interference.

- 1480
- 1481 1. ***Profiles should not be excluded if data gaps occur.*** There is useful data extending from  
1482 the surface up to the lower stratosphere, i.e. around 35 km or 5 hPa, that satisfies the four  
1483 key user groups of GRUAN data products. From Section 1.2 of GCOS-171 they are the  
1484 (i) climate detection and attribution community, (ii) satellite community, (iii) The  
1485 atmospheric process studies community, and (iv) numerical weather prediction (NWP)  
1486 community. Depending on where the data gaps occur and the extent of these data gaps,  
1487 there remains useable quality reference data that can still satisfy one or more of these four  
1488 communities. However, the satellite community will be the most affected by data gaps.
- 1489 1. Profiles with very large and intermittent data gaps should be identified and evaluated in  
1490 the annual reports and periodic audits. Ultimately, it is up to the end-user to determine  
1491 whether the data gaps should be excluded from their study.  
1492

### 1493 3.5 The GRUAN Standard Operating Procedures

1494

1495 GRUAN seeks to ensure that all sites operate to the same reference quality standard to guarantee  
1496 homogeneity of quality across the network. JOSIE and BESOS demonstrated that changes of an  
1497 ozonesonde instrument (e.g. different manufacturers) or operating procedures (e.g. incorrect  
1498 choice of sensing solutions, incomplete metadata, missing procedures) can have a large impact  
1499 on sonde data quality and thus influence the trends derived from such records. ASOPOS  
1500 demonstrated that after standardization and homogenization improvement of precision and  
1501 accuracy by about factor 2 might be gained. The JOSIE-1996 results show that differences  
1502 between the ECC ozone sensors types are largely due to differences in the preparation and  
1503 correction procedures applied by the different sites [Smit et al., 2000]. The WMO/GAW SOPs  
1504 are designed to reduce random errors by maintaining consistent and reproducible ozonesonde

1505 measurements. Standardization of the SOPs has been shown to improve the precision and  
1506 accuracy to less than  $\pm 5\%$ , while non uniformity in SOPs will lead to inhomogeneities in the  
1507 time series and between station data records [Smit et al, 2007, Deshler et al, 2008].  
1508

### 1509 **GRUAN protocol**

1510  
1511 GRUAN strongly recommends that Ozonesonde Programmes use the WMO/GAW ozonesonde  
1512 conditioning and preparation procedures outlined in detail in Annex A of GAW Report No. 201.  
1513

1514 Associated with the SOPs is a check list to help ensure that the site operators follows the  
1515 WMO/GAW ozonesonde conditioning and preparations procedures in a consistent manner. The  
1516 GRUAN check list (Appendix A-1) has been designed to be a guide to certify that SOPs are  
1517 being followed correctly. It is strongly recommended that potential site candidates use the  
1518 GRUAN check list in place their own SOPs, but it is not required as long as sites can  
1519 demonstrate that WMO/GAW SOPs are being followed and all essential metadata are recorded.  
1520

### 1521 **Refurbished Sonde SOPs**

1522 Refurbished sensors must follow more rigorous conditioning and testing. The ASOPOS panel  
1523 concluded that at present it is not clear in how often recovered ozonesondes can be re-used after  
1524 reconditioning. Currently there are no quality assurance standards for refurbished sensors and a  
1525 number of ozonesonde sites fly refurbished sondes using their own set of SOPs. Sites risk  
1526 potentially introducing artifacts in the data records if the re-conditioning procedures are not done  
1527 properly. A basic set of SOPs for refurbished sensors can be found in Appendix A-2, although  
1528 manufacturer SOPs should not be discounted. Further discussion on refurbished sensors can be  
1529 found in Section 4.5. GRUAN strongly recommends and encourages that JOSIE studies,  
1530 independent laboratory tests, and inter-comparison field measurements be conducted to establish  
1531 SOPs for refurbished sondes that GRUAN can draw on to incorporate across the Ozonesonde  
1532 Programme network.

## 1533 **3.6 The RSLaunchClient Utility**

1534 The RSLaunchClient utility will collect and manage uploaded metadata and ozonesonde PRD to  
1535 the GRUAN Lead Centre. Specifically, GRUAN Ozonesonde Programmes will be required to  
1536 provide essential metadata and PRD to the RSLaunchClient. GRUAN defines essential data as  
1537 input requirements to the RSLaunchClient. If one of the basic essential metadata variables is  
1538 missing a flag will be given or, in some cases, the entire profile will be rejected (e.g. if a  
1539 metadata variable required to calculate an uncertainty estimate is missing). Because each  
1540 ozonesonde ECC sensor is considered a new instrument it is essential that every singular feature  
1541 of each sensor is documented. The metadata represents all the characteristics that define each  
1542 unique ozonesonde and will be collected by the RSLaunchClient. Most of the metadata shall be  
1543 taken from the check list that has been designed to follow the WMO/GAW SOPs. The GRUAN  
1544 check lists for new and refurbished ozonesondes are provided in Appendix A-1 and A-2. The red  
1545 font in the check lists indicates that it is essential RSLaunchClient metadata. It is strongly  
1546 recommended that potential sites use the GRUAN check list in place of the manufacturer check  
1547 list.  
1548

1549 **3.6.1 Metadata for RSLaunchClient**

1550 To provide the best evaluation for the ozonesonde measurement uncertainty, a detailed  
1551 understanding of the instrumentation is required for the conditions under which it is used. The  
1552 ozonesonde metadata summarizes the unique characteristics of each ozonesonde instrument in  
1553 response to standard operational procedures, and it makes all factors that contribute to the  
1554 measurements traceable. Following the WMO/GAW SOPs a list of essential and desirable  
1555 metadata has been designed and is provided in Table 3.4 below. Desirable metadata (in blue) is  
1556 not required input to the RSLaunchClient. Profiles shall not be discounted if desirable metadata  
1557 is not included.  
1558

1559 Table 3.4 Essential and **Desirable** metadata variables specific to ECC sensors  
1560

- 1561 1. Station Name
- 1562 2. **GAW Number**
- 1563 3. Site Latitude [decimal deg (range -90:+90)]
- 1564 4. Site Longitude [decimal deg (range -180:+180)]
- 1565 5. Site Elevation [m]
- 1566 6. Re-conditioned Sonde: Y or N. If Y then the following information is required:
  - 1567 1. Date flown (YYYYMMDD)
  - 1568 2. Date found (YYYYMMDD)
  - 1569 3. Date returned (YYYYMMDD)
  - 1570 4. Date stored on shelf until ready for the 3-7 day pre-condition (YYYYMMDD)
  - 1571 5. Comments on overall ozonesonde/pump condition
  - 1572 6. 100 ppbv calibrated source current [ $\mu\text{A}$ ]
  - 1573 7. 100 ppbv ECC-sensor current [ $\mu\text{A}$ ]
  - 1574 8. Zero Ozone air calibrated source current [ $\mu\text{A}$ ]
  - 1575 9. Zero Ozone air ECC-sensor current [ $\mu\text{A}$ ]
- 1576 7. Date of Initial Pre-conditioning or Re-conditioning (done at least 3 days prior to flight):  
1577 YYYYMMDD
- 1578 8. Date of Secondary Preconditioning (if done): YYYYMMDD
- 1579 9. Launch Date: YYYYMMDD
- 1580 10. Launch time [GMT]: HH:MM:SS
- 1581 11. Sonde Type and Serial Number
- 1582 12. Radiosonde Type and Serial Number
- 1583 13. Interface Type and Serial Number
- 1584 14. Ground station system and software version
- 1585 15. Pump current [ $\mu\text{A}$ ]
- 1586 16. Pump Pressure [psi]
- 1587 17. Pump Vacuum [in Hg]
- 1588 18. Zero Ozone Source
- 1589 19. KI Solution Strength [%]
- 1590 20. Buffer amount
- 1591 21. Volume of cathode sensing solution [ $\text{cm}^3$ ]
- 1592 22. IB0
- 1593 23. IB1

- 1594 24. IB2
- 1595 25. Initial preparation Response Time [ $\mu\text{A}/\text{sec}$ ] = Time for ozone to drop from 4-1.5 microA
- 1596 26. Initial preparation current after Response Time [ $\mu\text{A}$ ]
- 1597 27. Flow rate: All 5 flow rates [ $\text{sec}/100\text{ml}$ ]
- 1598 28. Flow rate average [ $\text{sec}/100\text{ml}$ ]
- 1599 29. Lab Temperature during Flow rate test [ $\text{degC}$ ]
- 1600 30. Lab RH during Flow rate test [%]
- 1601 31. Lab Pressure during Flow rate test [hPa]
- 1602 32. Surface Pressure at launch site [hPa]
- 1603 33. Surface Temperature at launch site [ $\text{degC}$ ]
- 1604 34. Surface RH at launch site [%]
- 1605 35. Surface Wind Direction at launch site [ $\text{deg}$ ]
- 1606 36. Surface Wind Speed at launch site [ $\text{m/s}$ ]
- 1607 37. Inverse pump efficiencies factors
- 1608 38. Balloon Brand
- 1609 39. Balloon Pay-off Weight [grams]
- 1610 40. Independent measurements of total column ozone.
- 1611 41. Dobson or Brewer or other instrumentation to be defined in Section 8.3.

1612  
 1613 Variables specific to the radiosonde data stream, such as P-T-U calibrations, offsets, and  
 1614 uncertainty calculations, shall borrow from the Radiosonde Analysis Software in the GRUAN  
 1615 Radiosonde Technical Document (X.X.X).

### 1616 **3.7 The GRUAN Ozonesonde Analysis Software System (GOASS)**

1617 The GRUAN Ozonesonde Analysis Software System (GOASS) is the centralized data  
 1618 processing software that shall analyses the PRD of all certified GRUAN Ozonesonde  
 1619 Programmes sent out through the RSLaunchClient utility. Before processing the PRD, the  
 1620 GOASS reconciles the metadata received from the RSLaunchClient with those contained in the  
 1621 GOIMP. Any inconsistency is immediately reported, thus providing a near-real-time check of the  
 1622 measurement traceability and stability, as well as a quick identification of change. The GOASS  
 1623 must be transparent, i.e., must be developed and optimized in consultation with all GRUAN  
 1624 Ozonesonde Programme Representatives/investigators, as well as the GRUAN Lead Centre,  
 1625 WG-GRUAN, and TTS. These investigators shall meet regularly to discuss the implementation  
 1626 of updates to the GOASS, and whether processing changes pertain to one or all of the GRUAN  
 1627 Ozonesonde Programmes. The output of the GOASS consists of certified ozonesonde metadata,  
 1628 CRD, and SGDP defined in Sections 3.5 and 3.6.

1629  
 1630 The basic principles driving the technical programming of the GOASS are as follows:

- 1631
- 1632 1. Each GRUAN ozonesonde instrument shall be considered as a unique instrument within
- 1633 the network.
- 1634 2. Each GRUAN ozonesonde may experience instrumentation change over time.
- 1635 3. Each GRUAN ozonesonde shall use up-to-date SOPs recommended by WMO/GAW
- 1636 across the network.
- 1637

1638 The need for centralized processing therefore implies a very stringent data processing approach.  
1639 The GOASS must integrate correction methods and associated uncertainties that are accepted by  
1640 GRUAN and user communities as being appropriate for the science application foreseen. It is  
1641 therefore the GRUAN Lead Centre, TTS, and GRUAN Ozonesonde Programme  
1642 Representative's joint responsibility to develop and maintain the operational GOASS. Failure of  
1643 GRUAN Ozonesonde Programmes to use an operational version of the RSLaunchClient and  
1644 GOASS will result in delivery delays of the ozonesonde SGDP, and therefore can result in the  
1645 cancelation of the Programme's certification at the time of its audit.

1646  
1647 The PRD and associated metadata accepted by the RSLaunchClient will be processed by the  
1648 Lead Centre using the GRUAN Ozonesonde Analysis Software System (GOASS). The GOASS  
1649 shall perform the following steps to transform the PRD to the final Level 2 GRUAN standard  
1650 ozonesonde product (SGDP) (defined in this Document as a collection of profile measurements  
1651 of ozone, meteorological variables from the radiosonde and uncertainties):

- 1652
- 1653 1. Apply filtering criteria to test the performance of an individual ECC sensor, summarized  
1654 in Table 3.5 below. Aspects of the conditioning process should fit within the following  
1655 specific thresholds. GRUAN site operators shall use these threshold criteria to gauge the  
1656 quality of the ECC sensor and perform repeat tests if necessary to bring the ECC sensor  
1657 into compliance. Ideally, ozonesonde raw data should not be uploaded to the  
1658 RSLaunchClient if certain threshold criteria are violated.

1659  
1660

1661 Table 3.5 Threshold criteria for ECC ozonesondes used by the RSLaunchClient to test the  
 1662 performance quality of each sensor. These are specifically for SPC and ENSCI sensor types.

Test Indicator	Threshold Criteria	Action if violated
Average pump flow rate	Within 26-36 sec/ml	Flag and record in metadata
Response Time	20-30 sec	Flag and record in metadata
Pump temperature	273-315 K (-15 – 40 C)	Flag for ozonesonde datum exceeding threshold.
Background $I_{B0}$	0-0.05 $\mu$ A	See 1.1
Background $I_{B1}$	0-0.1 $\mu$ A	Flag and record in metadata
Background $I_{B2}$	0-0.1 $\mu$ A	Flag and record in metadata
Background $I_B$	Should be $I_{B0}$ or the minimum of $I_{B0}$ , $I_{B1}$ , and $I_{B2}$ if $I_{B0} > 0.05 \mu$ A	See 1.1
Pump motor current	> 100 $\mu$ A for SPC, > 90 $\mu$ A for ENSCI	Flag and record in metadata
Pump pressure	> 10 psi	Flag and record in metadata
Pump vacuum	< 20 in Hg	Flag and record in metadata
KI Solution	0.5% buffered for ENSCI; 1.0% buffered for SPC	Should be always be correct for GRUAN certification. For historic data, where applicable, transfer functions shall be applied.
Pump Correction Factors (PCF)	Komhyr [1986] values for SPC-6A and Komhyr et al. [1995] values for ENSCI	Ozone values shall be recalculated using the correct (PCF)

- 1663  
 1664  
 1665  
 1666  
 1667  
 1668  
 1669  
 1670  
 1671  
 1672  
 1673  
 1674  
 1675  
 1676  
 1677
- 1.1  $I_{B0}$  shall be used as the final background,  $I_B$ , in the ozone equation (addressed in Section 2.2). For the case where  $I_{B0} > 0.05 \mu$ A GOASS shall recalculate ozone using the minimum of  $I_{B0}$ ,  $I_{B1}$ , and  $I_{B2}$  as  $I_B$ . If that minimum background current exceeds the 0.05  $\mu$ A threshold then GOASS shall recalculate ozone using  $I_B=0.05 \mu$ A shall be used and flagged in the metadata. It should be recorded in the metadata which background is used as  $I_B$ .
  2. GOASS shall apply the RH correction,  $C_{PH}$ , explained in detail in Section 2.4. The final flow rate,  $\Phi=(\text{mean flow rate}) \cdot C_{PH}$ , shall be used in Equation 2.1.1 to calculate the Level 2 ozone partial pressure product.
  3. Radiosonde/Ozonesonde offsets in height and pressure, if any, shall be documented in the metadata and geopotential heights shall be recalculated, in accordance with the GRUAN Radiosonde Technical Document (X.X.X).
  4. Adjusted pump temperatures using Equation 2.6.5 and sub-equations shall be calculated. That along with the measured pump temperatures shall be used to calculate two ozone partial pressures.

- 1678 5. After the above corrections are applied ozone partial pressure shall be recalculated using  
1679 Section 2.1 Equation 1 in two ways: (i) using the original measured pump temperature  
1680 and (ii) the adjusted pump temperature based on bullet 4 above.
- 1681 6. Uncertainties for each measured parameter in the ozone partial pressure equation shall be  
1682 calculated and are defined in the subsections of Section 6.
- 1683 7. The individual uncertainties shall be used to calculate the ozone partial pressure for each  
1684 ozone datum, as defined in Section 6.1.
- 1685 8. A total column product shall then be calculated based on the processing protocol defined  
1686 in Section 2.7.

### 1687 **Flagged Data**

1688 Data that are not within threshold levels itemized in Table 3.5 shall not be rejected but must be  
1689 flagged and documented in the final archived metadata. Flagged metadata shall be included as a  
1690 diagnostic tool in each GRUAN Ozonesonde Programmes annual report. Audits shall use the  
1691 statistics gathered on flagged metadata and the SGDP to help evaluate the continuity of GRUAN  
1692 Ozonesonde Programmes.

### 1693 **3.8 GRUAN ozonesonde calibration management**

1694 Ozonesonde ground stations generally do not require calibration at the manufacturing,  
1695 instrumentation, or operational levels. Calibration of the ECC sensor comes from adhering to the  
1696 SOPs and completing the metadata check list requirements. The results of the conditioning  
1697 procedures summarizes the unique responses of the individual sonde to a standard fixed set of  
1698 operating procedures. At the time of this document, there is no precedent or standard rules that  
1699 requires sites to test or calibrate aspects of the ground station equipment, nor is there a  
1700 mechanism to ensure equipment standards and quality. It would ideal to establish guidelines by  
1701 which a GRUAN Ozonesonde Programme can calibrate its ground station equipment such that  
1702 sources of error and uncertainty can be further identified, traced, and included as part of the  
1703 uncertainty budget for ozonesondes.

### 1704 **World Calibration Facility for Ozonesondes (WCFOS)**

1705 The World Calibration Center for Ozonesondes (WCCOS) at the Forchungszentrum, Jülich,  
1706 Germany periodically conducts inter-comparison experiments (JOSIE) to establish and maintain  
1707 quality assurance of the ozonesondes sensors. JOSIE performs routine testing of existing and  
1708 newly manufactured ECC ozone sensors to (i) check the instrument performance in a controlled  
1709 environment, (ii) maintain up-to-date SOPs, (iii) test individual ECC sensor capabilities, and (iv)  
1710 develop uncertainty estimates for the individual instrument parameters. The WG-GRUAN shall  
1711 use findings from the JOSIE reports to evaluate current best practices and whether changes to the  
1712 ozonesonde SOPs or processing procedures need to change. Members of the WG-GRUAN are  
1713 encouraged to participate in JOSIE initiatives to keep abreast of new findings. It is highly  
1714 desirable for GRUAN sites to endorse and participate in JOSIE-led activities.

### 1715 **Calibration of the ozonizer test unit**

1716  
1717  
1718  
1719

1720 The ozonizer used to condition and prepare an ECC sensor does not generate a traceable amount  
1721 of ozone. Comparisons against an independent calibrated reference, such as a TEI surface ozone  
1722 monitor, to generate a known ozone amount would be very useful. It would be desirable for sites  
1723 to provide traceable ground/instrument checks, such as a surface ozone monitor (e.g. TEI) at the  
1724 time of each profile measurement, prior to launch and independent of the manufacturer. In the  
1725 case of refurbished ECC sensors it is strongly recommended that a calibrated source of ozone to  
1726 test the instrument performance be used and included as part of their SOPs.  
1727

### 1728 **3.9 Ozonesonde Programme versioning system**

1729 A system of traceable version numbers and dates for all GRUAN Ozonesonde Programmes shall  
1730 be developed to allow for a full identification and tracking of changes in SOPs, and data  
1731 processing since the initial certification. Every reprocessing of the metadata, CRD, and SGDP  
1732 must be reflected in an increment in the data version and an update to the date of creation by the  
1733 GOASS (see file naming convention in Section 3.4.5) as prescribed in the data versioning  
1734 protocols developed by the GRUAN Lead Centre. Such data updates must also be communicated  
1735 to users who have accessed earlier versions of the data and who have voluntarily registered to  
1736 receive notifications of such data updates (see Section 8.6 of GCOS-171). For this reason it is  
1737 also important that all older versions of any data set are always archived and made available  
1738 through the GRUAN Lead Centre's archive.  
1739

### 1740 **3.10 GRUAN Ozonesonde Programme auditing**

1741 Certification of GRUAN sites will not be a single event. GRUAN sites will be audited by  
1742 members of the WG-GRUAN at 3-4 year intervals to ensure that the programme continues to  
1743 meet GRUAN standards.  
1744

1745 The audit will involve:

- 1746
- 1747 1. A review of the sites annual reports.
- 1748 2. An ozonesonde launch in front of WG-GRUAN auditors that demonstrates that the SOPs  
1749 are being followed in accordance with Section 3.5.
- 1750 3. Check lists will be reviewed against the GRUAN Check lists if not used.
- 1751 4. Discussions with the scientists responsible for the measurement programmes at the site.
- 1752 5. In the eventuality of identified site problems the following protocols shall be followed  
1753 (taken from Section 5.6 of the GCOS-171):
  - 1754 1. Should a measurement programme at an existing GRUAN site show significantly  
1755 reduced observational capability over more than a year, as evaluated by the criteria  
1756 listed above, the WG-GRUAN and Lead Centre shall investigate the circumstances at  
1757 that site, and, if needed, exclude that programme from the GRUAN certification for  
1758 that site. The WG- GRUAN and Lead Centre shall work proactively with sites to  
1759 resurrect such programmes providing training, technical and in-kind support as  
1760 practical and as needed.
  - 1761 2. Should the overall contribution of a site be deemed sufficiently diminished to call into  
1762 question its continued presence in the network, the site shall be informed immediately

1763 in writing. The site shall be given six months to form a capabilities recovery plan, in  
1764 consultation with the Lead Centre and WG-GRUAN. Should this plan be accepted the  
1765 site will have no more than two calendar years from its acceptance to implement  
1766 agreed key aspects. In the eventuality that this is not achieved, the site shall be  
1767 suspended with an invitation to submit anew at such a time as problems are remedied.  
1768 3. An existing GRUAN site may also request the temporary suspension of some or all of  
1769 the measurement programmes at that site from GRUAN certification. This could  
1770 occur for example in cases of unforeseen budget limitations, non-availability of  
1771 personnel or some other unavoidable circumstance affecting the measurement  
1772 programmes at the site. Such a request must be submitted in writing to the  
1773 WG-GRUAN and the Lead Centre. At some later time, should the site request  
1774 recertification of those measurement programmes previously suspended, the  
1775 procedure for certification as outlined in Figure 2 of GCOS-171 shall be followed.  
1776 4. A certified GRUAN Ozonesonde Programme may also request a temporary  
1777 suspension of its certification. This could occur, for example, in case of unforeseen  
1778 budget limitations, non-availability of personnel or some other unavoidable  
1779 circumstance affecting the measurement programme. Such a request must be  
1780 submitted in writing to the WG-GRUAN, Lead Centre, TTS. The normal procedure  
1781 for certification should be followed if re-certification is later requested.

1782  
1783 Along with the cooperation and goodwill of participating sites, nations, and individuals, the  
1784 establishment of these GRUAN site assessment and certification guidelines provides one of the  
1785 main foundations for ensuring that GRUAN meets its goals as a climate observing network.

## 1786 4 GRUAN OZONESONDE INSTRUMENTATION

1787 As described in Section 2 (and elsewhere) of the GCOS-171, one key requirement of GRUAN  
1788 instruments is to provide reference measurements, i.e., using principles based on key concepts in  
1789 metrology such as (but not limited to) traceability. Traceability must apply at all levels of the  
1790 data acquisition and processing chain, including instrumentation. Therefore to ensure full  
1791 traceability, a complete and accurate description of each certified GRUAN Ozonesonde  
1792 Programme system must be provided in GOIMP (defined in Section 3.2). An entire ozonesonde  
1793 system comprises the following components:  
1794

- 1795 1. Electrochemical concentration cell (ECC) ozonesonde which is encased in a molded  
1796 polystyrene weatherproof box for ascent into the lower stratosphere
- 1797 2. Radiosonde
- 1798 3. Interface electronics, if applicable, to couple the ECC ozonesonde to the radiosonde.
- 1799 4. A ground station for receiving data provided by the radiosonde manufacturer. The ground  
1800 station consists of a portable, tripod mounted, antenna with built-in pre-amplifier, and a  
1801 long coaxial cable that connects the antenna to a 403 MHz receiver.
- 1802 5. A laptop with pre-installed data acquisition and processing software. This allows data to  
1803 be received and processed during the balloon flight.
- 1804 6. A 1200 baud modem that connects the laptop to the 403 MHz receiver.

1805

1806 Refer to the GRUAN Radiosonde Technical Report (X.X.X ) for instrument details pertaining to  
1807 radiosondes and their ground stations and data acquisition systems. Refer to the ECC manuals  
1808 for information pertaining to the materials and electronics of the ECC sensor mainframe, and  
1809 type interface circuitry which couples the sensor to the particular type of meteorological  
1810 radiosonde [e.g. DMT, 2014; SPC, 1999].  
1811

1812

1813 The requirements and recommendations on ozonesonde instrumentation provided in this section  
1814 apply only to the ozonesonde techniques recognized to be mature enough to be providing  
1815 reference measurements of ECVs of highest-enough priority for GRUAN. As of this document,  
1816 these include the SPC and ENSCI instruments coupled with the Vaisala and iMET radiosondes  
1817 and ground stations and associated data acquisition and processing software. Other radiosonde  
1818 and ground station data acquisition system packages, addressed in Section 4.4, shall be included  
1819 as they are assessed and recognized by the Lead Centre and WG-GRUAN to be providing  
1820 products compliant with GRUAN measurement standards. It is important to mention that  
1821 GRUAN shall not prescribe any instrumentation system and setup in particular. Rather, GRUAN  
1822 shall provide simple and practical recommendations that encourage sites to use the best practices  
1823 in full compliance with the requirements and recommendations detailed in this Guide.

1824

### 1824 4.1 General considerations from Section 6.1 of the GRUAN *Guide to* 1825 *Operations (GCOS-171)*

1826

1827 Periodic reviews of ozonesonde instrumentation likely to be of use within GRUAN shall be  
1828 undertaken. It must also be recognized that not all Ozonesonde Programmes within GRUAN will

1829 operate the same ozonesonde instrumentation and ground station system. GRUAN will not  
1830 prescribe the use of specific ozonesonde instruments and ground station systems in the network  
1831 since the emphasis is not on prescribing an instrument, but rather on prescribing the capabilities  
1832 required of an instrument and allowing individual sites to select an instrument that achieves those  
1833 capabilities. That selection will be influenced by the requirements and recommendations put  
1834 forth by this document, and other scientific, programmatic, and practical constraints on the site.  
1835 That said, the fewer the number of different types of instruments and measurement techniques  
1836 deployed within and among GRUAN Ozonesonde Programmes, the more likely network  
1837 homogeneity will be achieved.

1838  
1839 A number of criteria should be considered when selecting ECC ozone sensor instruments for use  
1840 in GRUAN including: instrument heritage (i.e. maturity), sustainability, robustness of  
1841 measurement uncertainty, and manufacturer support.

1842  
1843 Since 1996, the Forschungszentrum, Jülich, Germany has been the site of the WCCOS. The first  
1844 Jülich Ozone Sonde Inter-comparison Experiment (JOSIE) (1996) has shown that ECC ozone  
1845 sensors that performed with the best precision and accuracy were the Science Pump Corporation  
1846 (SPC) and ENSCI instrument manufacturers [Smit et al., 2000]. The 1996 experiment calculated  
1847 a precision to within  $\pm(3-4)\%$  and an accuracy to within  $\pm(4-5)\%$ . Subsequent JOSIE-led  
1848 activities have included both types of ECC sensors in their inter-comparisons.

1849  
1850 GRUAN recognizes that ECC sensor technology is constantly evolving and that not all sites  
1851 within GRUAN will operate the same ECC sensor, e.g. a new site may decide to adopt a new  
1852 ECC-sensor that has not been yet been included in JOSIE studies, or an existing site may  
1853 continue to use an older manufacturing model or obsolete sensing solution (e.g. 2% unbuffered)  
1854 to avoid potentially introducing a discontinuity in the measurement time series.

1855

#### 1856 **4.1.1 Instrument Selection**

1857 As of this Document there are two ECC sensors on the market:

- 1858 a. Science Pump Corporation (SPC)
- 1859 b. ENSCI

1860

- 1861 1. Both manufacturer types are considered the leading industry standard for ECC  
1862 ozonesondes and have a long heritage of launches.
- 1863 2. The commercial demand for SPC and ENSCI is sufficient to support the production and  
1864 use of the instrument for the expected multi-decade deployment within GRUAN.
- 1865 3. There is no reason to suspect that both instrument manufacturers will stop production in  
1866 the foreseeable future, even if a newer (but not necessarily better) instrument is  
1867 developed and marketed.
- 1868 4. All ozonesonde stations with long-term ECC records use one or both types and are  
1869 archived at SHADOZ, NDACC, and the WOUDC.
- 1870 5. Finally, all WMO-supported ECC inter-comparison studies (JOSIE), campaigns  
1871 (BESOS) and other laboratory and field studies have included these two manufacturing  
1872 types. Thus, there is a substantial body of literature documenting its performance and  
1873 measurement uncertainty.

1874 6. Through JOSIE and independent dual-launch studies, the precision and accuracy claims  
1875 for both instruments and its resultant data is sufficiently robust and meets the uncertainty  
1876 and stability standards under Section 4.1 of GCOS-171.

1877  
1878 In the event that a new ECC ozone sensor is commercially developed, GRUAN expects the  
1879 manufacturer to (i) actively participate in JOSIE and other instrument inter-comparisons, (ii) be  
1880 willing to disclose the necessary information required to form a fully traceable chain of sources  
1881 of measurement uncertainty in accordance with the GCOS-171 mandatory operating  
1882 requirements, and (iii) make available the algorithms used for corrections within the data  
1883 processing software to conduct uncertainty analysis. In accordance with GCOS-171 guidelines, it  
1884 is a 'fundamental requirement that the information required to reprocess the data at any time in  
1885 the future must be made available (though not necessarily publicly available)'.  
1886

## 1887 **4.2 Measurement Redundancy**

1888 “Having different instruments at GRUAN sites measuring the same atmospheric parameters will  
1889 be invaluable for identifying, understanding and reducing systematic effects in measurements”  
1890 - GCOS-171  
1891

1892 Examples of redundant instruments that measure profile ozone are the ozone Lidar and  
1893 Microwave Radiometer. Other ozone monitoring instruments to consider that can complement  
1894 ozonesonde profile measurements are the TEI surface ozone monitor, and UV Vis  
1895 instrumentation. All these instruments can provide uninterrupted hours of measurements at one  
1896 given location. Unlike these fixed located instruments, balloon-borne ozonesondes provide in-  
1897 situ measurements at varying locations and altitudes with time. The challenge therefore is to  
1898 match the ozonesonde altitude and time with those other instruments with careful considerations  
1899 about the geographic displacement from the ground-based instrument site. Section 6.4.2. of  
1900 GCOS-171 provides an overview of the characteristics of Lidar and microwave instrumentation.  
1901 Methods on resolving the time/altitude differences from these instruments shall draw on  
1902 information found in the GRUAN technical documents for Lidar and Microwave Radiometers.  
1903 GRUAN shall draw on methods developed by Calisesi et al. [2005], Bodeker et al. [2013],  
1904 Hassler et al., [2008] and references therein, that create site atmospheric state best estimates  
1905 (SASBE) of ozone profiles from combining ozone instrumentation of varying temporal and  
1906 spacial resolutions to provide objective evaluation of ozonesonde performance. Ozonesonde  
1907 measurements themselves may be part of SASBE.  
1908

## 1909 **4.3 The SCIENCE PUMP CORPORATION ozonesonde**

1910 The earliest Science Pump Corporation (SPC) ECC ozonesonde measurements occurred in the  
1911 late 1960's [Komhyr, 1969]. Table 1 from Johnson et al. [2002] summarizes the model  
1912 production dates and design changes from the earliest SPC design (SPC-1A). The first known  
1913 operating guidelines for preparing ozonesondes for flight was created for the now retired SPC-  
1914 4A model in the NOAA technical memorandum [Komhyr, 1986]. The current manual has been  
1915 optimized for the SPC-6A model design [SPC Manual, 1999].  
1916

1917 **GRUAN protocol procedure**

1918

1919 As of this document, the GOASS shall process PRD from SPC-4A models and higher to produce  
1920 the ozonesonde SGDP using procedure protocols established in this document. All other historic  
1921 SPC profiles from older SPC models should be inventoried and properly conserved until such  
1922 time as their information content can be evaluated, assessed, and assigned uncertainty estimates  
1923 that conform to GRUAN reference standards and guidelines.

1924

1925 While the SPC modifications over time improved ECC performance, error characterization in  
1926 models older than SPC-4A are not as well known. The first SOP manual was conceived with the  
1927 SPC-4A model design in mind and changed with model design as they were altered to optimize  
1928 performance. Given that these older SPC models no longer exist and are no longer flown, JOSIE-  
1929 type studies or campaigns are necessary to determine error estimates or empirical corrections to  
1930 all historic instrumental parameters.

1931 **4.4 The ENSCI ozonesonde**

1932 ENSCI Corporation started in the late 1980's with similar ECC sensor instrument configuration  
1933 to that of the SPC-5A model (refer to Table 1 of Johnson et al., [2002]). Komhyr [1997]  
1934 published the first ENSCI operations handbook for the 2Z model. There is no significant  
1935 instrumental differences between the Z and 2Z models [Bryan Johnson/NOAA, personal  
1936 communication]. The Z model is configured to be compatible with interface boards of other  
1937 ground station systems (e.g. Vaisala) while the 2Z has a built-in V7 interface board compatible  
1938 with the iMET ground station.

1939 Since the late 2000's Droplet Measurement Technologies (DMT) took over the manufacturing of  
1940 ENSCI ECCs. The model design has remained unaltered at the helm of DMT, thus GRUAN does  
1941 not make a distinction between the two companies. As of this document, the most up to date  
1942 ENSCI manual has been published by DMT [2014] and includes much of the WMO/GAW SOP  
1943 recommendations and protocols. As of this Document, ENSCI has separated from DMT and is  
1944 once again it's own manufacturing entity.

1945

1946 **GRUAN protocol procedure**

1947

1948 The GRUAN archive shall accept ENSCI Z, 2Z ozonesonde instrument profiles to produce the  
1949 ozonesonde SGDP.

1950

1951 **4.5 A typical GRUAN ozonesonde data acquisition systems**

1952 The ozonesonde is interfaced with a radiosonde and uses its data acquisition system to transmit  
1953 and record the ozone current and other parameters that calculate the ozone partial pressure (see  
1954 Equation 1 in Section 2.1). The ozonesonde/radiosonde equipment and data acquisition system  
1955 shall also be referred to as the 'ozonesonde ground station'. From to Section 6.1 of GCOS-171

1956

1957 “GRUAN will not prescribe the use of specific instruments in the network since the  
1958 emphasis is not on prescribing an instrument, but rather on prescribing the capabilities

1959 required of an instrument and allowing individual sites to select an instrument that  
1960 achieves those capabilities.”

1961  
1962 As of this Document, there are a number of ozonesonde/radiosonde ground station systems  
1963 operating with varying degree of publicly available documentation. These include Vaisala  
1964 (Finland), iMET (USA), Lockheed-Martin-Sippican (LMS, USA), Meisei (Japan), Modem  
1965 (France), and Chang Feng (China). The Vaisala type ground station system is the most  
1966 commonly used, having a heritage of long term records of ozonesonde and radiosonde  
1967 measurements. Specific to radiosondes there is a large body of literature that have characterized  
1968 the uncertainties and biases among the Vaisala models (Dirksen et al., [2014] and references  
1969 therein; Hurst et al. [2011]; Nash et al. [2006; 2011]; Steinbracht et al., [2008] and references  
1970 therein; and Vömel et al. [2007]). Hurst et al. [2011] and Stauffer et al [2014] were among the  
1971 first inter-comparison studies of iMET and Vaisala models. Both iMET and Vaisala adhere to the  
1972 instrument selection requirements addressed in Section 6.1 in GCOS-171. This includes, but is  
1973 not limited to, information content, instrument heritage (e.g., maturity), sustainability (e.g.  
1974 sufficient commercial demand), robustness of measurement uncertainty, and manufacturer  
1975 support. Both ozonesonde ground station systems are known to provide all the essential raw data  
1976 and metadata listed in Tables 3.1 and 3.4, respectively

1977  
1978 As of this Document, there is varying degree of documentation that is publicly available on the  
1979 other supporting ozonesonde/radiosonde ground station systems mentioned above. However,  
1980 meeting the GCOS-171 instrument selection criteria and GRUAN data quality assurance and  
1981 measurement standard policies can be assured provided that the manufacturer is:

- 1982
- 1983 • Committed to improving the performance of its instrument.
  - 1984 • Willing to provide essential GRUAN raw data and metadata listed in Tables 3.1 and 3.4,  
1985 respectively.
  - 1986 • Prepared to actively participate in instrument inter-comparisons (e.g. JOSIE) and field  
1987 campaigns (e.g. BESOS).
  - 1988 • Willing to disclose the necessary information required to form a fully traceable chain of  
1989 sources of measurement uncertainty (e.g. releasing SOPs and algorithms used for any  
1990 corrections within its data processing software).

1991  
1992  
1993 **GRUAN procedure protocol**

- 1994
- 1995 1. At a minimum, GRUAN requires that candidate sites use ground stations that provide the  
1996 essential metadata (Table 3.4) and raw data (Table 3.1). These parameters are critical to  
1997 characterizing each individual ozonesonde.
  - 1998 2. GRUAN shall encourage all ozonesonde/radiosonde ground station manufacturers to  
1999 participate in JOSIE-led activities.
  - 2000 3. GRUAN shall encourage ozonesonde/radiosonde ground station manufacturers to provide  
2001 documentation on laboratory and dual sonde launches to demonstrate that the precision  
2002 and accuracy fits within  $\pm(3-4)\%$  and  $\pm(4-5)\%$  of the JOSIE results, respectively. These  
2003 results have been determined by Smit et al. [2000] using the leading SPC and ENSCI  
2004 ECC sensors (see Section 4.1.1).

2005

## 2006 **4.6 Refurbished Ozonesondes**

2007 The ASOPOS panel concluded that at present it is not clear in how often recovered ozonesondes  
2008 can be re-used after reconditioning. The general recommendation by the ASOPOS panel is not to  
2009 fly re-used ECC-sondes, however, for a number of ozonesonde sites it is the most cost-effective  
2010 way to ensure financial stability of their programme and maintain their ozonesonde launch  
2011 schedule. GRUAN shall (i) encourage sites at unique locations (refer to Section 3.2.1 on added-  
2012 value criteria) that regularly launch re-used sondes to apply to become a GRUAN site and (ii) not  
2013 prohibit existing Ozonesonde Programmes from including data from refurbished ozonesondes,  
2014 provided that all operating conditions set forth by this Document are met.

2015  
2016 Refurbished sensors falls under one of the “9 items” under managing changes in Section 7 of this  
2017 report. Thus, established GRUAN Ozonesonde Programmes that wish to include refurbished  
2018 sensors falls under the guidelines of a “change event” and programmes shall follow steps in  
2019 Section 7.1 to include refurbished ozonesondes into their programme. For new candidate sites  
2020 seeking to become a GRUAN site this information should be included as part of their GOIMP.

2021  
2022 For individual GRUAN Ozonesonde Programmes re-using ECC-sensors, the re-conditioning  
2023 SOPs of recovered sondes should be done by well-skilled and trained personnel and be done in  
2024 such a way that the resulting metadata is always within the threshold criteria defined in Table 3.5  
2025 and does not introduce artifacts in their long term ozone records. For refurbished ozonesondes it  
2026 is recommended that Ozonesonde Programmes following the modified NOAA prescribed re-  
2027 conditioning instructions found in Appendix A-2 or re-conditioning procedures as given by the  
2028 sensor-specific manufacturer.

2029  
2030 In recognition of the heterogeneity of the GRUAN ozonesonde network, the WG-GRUAN and  
2031 GRUAN Lead Centre shall evaluate individual candidate sites ability to launch refurbished  
2032 sondes based on the following

2033 • Sites seeking to become a GRUAN site will first be assessed according to their ability to  
2034 meet the mandatory operating protocols defined in Section 5.3 of GCOS-171 and  
2035 specifically 3.1 of this report, and then according to the added value they bring to the  
2036 network, as defined in Section 3.2.1 of this document. This will enable candidate sites to  
2037 operate their ozonesonde programme to GRUAN standards.

2038 • In assessing the value a specific site adds to the network, the WG-GRUAN and Lead  
2039 Centre will base decisions on sound scientific research while exercising its discretion in  
2040 evaluating the proposal against the criteria defined in value-added assessment in Section  
2041 3.2.1 of this document. Consideration shall be given to, but not be limited to, the  
2042 following:

- 2043 ◦ Body of peer-reviewed literature using refurbished sondes.
- 2044 ◦ Historical data – sites with long term homogenous data records is a desirable factor.
- 2045 ◦ Operation set-up
- 2046 ◦ The ability and skill of site operators to re-condition sensors following re-  
2047 conditioning operating protocols (Appendix A-2 or manufacturer specific).

- 2048           ◦ The availability of an ozone calibrator to assess the performance of each re-used
- 2049           sensor.
- 2050           ◦ Funding constraints.
- 2051           ◦ Launch schedule which is a defining factor in assessing the extent to which the
- 2052           candidate site can become a fully operational GRUAN Ozonesonde Programme.
- 2053
- 2054

2055 GRUAN Ozonesonde Programmes shall be responsible for conducting tests to ensure that the  
2056 continuity of the data record is not compromised. Sites must clearly demonstrate that each  
2057 refurbished ozonesonde is measuring ozone with an accuracy and uncertainty similar to that of a  
2058 new ozonesonde. This can be done using calibrated ozone instrumentation, e.g. TEI, that tests the  
2059 sensor performance against known quantities of ozone, and through duel sonde inter-  
2060 comparisons.  
2061

## 2062 **5 OZONESONDE MEASUREMENT SCHEDULING**

2063 As detailed in Section 5.2.1 of GCOS-171, a fully equipped GRUAN site is required to make  
2064 weekly ozone profile measurements. While it is not stipulated whether such measurements  
2065 should be made using ozonesondes, lidar or microwave radiometer, the expectation is that an  
2066 ozonesonde measurement programme would be a staple of an GRUAN vertical ozone profile  
2067 measurement programme.

2068 Scientifically, measurement scheduling for GRUAN ozonesonde programmes is likely to be  
2069 driven by:

- 2070 • The needs of the stratospheric ozone change detection community. Ozonesonde flights need  
2071 to be made sufficiently frequently to provide ozone time series suitable for detecting trends  
2072 in the vertical distribution of ozone.
- 2073 • The needs of the air quality assessment community. Because ozone is a component of urban  
2074 air quality, ozonesonde measurements need to be made sufficiently frequently to support air  
2075 quality process studies.
- 2076 • The needs of the satellite validation community. To the extent possible ozonesonde launches  
2077 should be timed to coincide with overpasses of satellite which are also making  
2078 measurements of the vertical profile of ozone.

2079 Ozonesonde protocols will continue to develop over time and, in the case of conflict between  
2080 GCOS-171 guidelines and this Ozonesonde Technical Document, the schedule outlined in this  
2081 Document shall take precedence (see Section 7.5 of GCOS-171).

### 2082 **5.1 General considerations from Section 7 of the GRUAN Guide**

#### 2083 **Responsibilities**

- 2084 • The candidate site shall work with the WG-GRUAN and assigned TTS to define  
2085 measurement schedule that allow the resultant ozone data products to best capture all  
2086 important scales of temporal variability, both for trend analysis and for process  
2087 understanding.
- 2088 • In designing the Ozonesonde Programmes measurement schedule it will be necessary for  
2089 the TTS and WG-GRUAN to work closely with individual sites since scheduling is likely  
2090 to be site specific. For example, some sites are more likely to (i) experience specific or  
2091 unique atmospheric conditions related to the understanding of associated processes  
2092 compared to other sites, (ii) be more financially constrained compared to other sites, and  
2093 (iii) experience limit operating capabilities compared to other sites.
- 2094 • These schedules should be conservative in the early stages of GRUAN because schedules  
2095 will vary and depend on both the system being sampled (e.g. greater sampling being  
2096 required in seasons of greater variability) and financial constraints (e.g. the costs of  
2097 expendables). Thus, it is important to consider the added value of a site to the GRUAN  
2098 ozonesonde network (see Section 3.2.1).
- 2099 • Given that task teams have a finite operating life, should the TTS no longer exist, this  
2100 scheduling guidance responsibility shall fall to selected members of the WG-GRUAN  
2101 who may include participants from the wider GRUAN community to assist with revising  
2102 measurement scheduling protocols.  
2103

## 2104 **Guiding Principles**

2105

- 2106 • Where available, scientific and statistical studies shall inform the process for establishing  
2107 ozonesonde measurement schedules. However, a sound scientific basis for the  
2108 measurement schedules discussed in this Document and in the GRUAN Guide to  
2109 Operations may not always be available and until they become available, the measurement  
2110 schedules must be considered to be preliminary.
- 2111 • The timing of an ozonesonde launch may be shifted to coincide with a satellite overpass  
2112 and in this way provide valuable high quality data for satellite validation. This will serve  
2113 the high priority satellite community.
- 2114 • Where possible, measurement schedules for redundant systems should be synchronized  
2115 so as to avoid sampling biases when combining the measurements into a single data  
2116 product.
- 2117 • Required measurement schedules may vary regionally and seasonally. In places and  
2118 seasons where the parameter being measured is more variable, measurements should  
2119 ideally be made more frequently.
- 2120 • Factors affecting trend detection: The magnitude of the variability, the autocorrelation,  
2121 the random error on the measurements, and the size and seasonality of the expected  
2122 ozone trends are the factors influencing the quality of trend detection that should guide  
2123 the development of measurement schedules
- 2124 • Measurement scheduling shall remain stable unless there is a clear requirement for  
2125 change, which would then have to be agreed with the relevant GRUAN sites.  
2126 Amendments to the GRUAN measurement scheduling protocol shall follow guidelines  
2127 outlined in Section 7.1 of this report.

2128

2129 Ozonesonde sites vary in levels of maturity (length of operation), resource (launch frequency),  
2130 and possess varying levels of infrastructure (air-conditioned versus ambient laboratory  
2131 conditions) and financial support (piece-meal, intermittent, or core funding). Consideration will  
2132 be given to sites with limited funding to operate at the optimal launch frequency determined by  
2133 the task team.

## 2134 **5.2 GRUAN ozonesonde measurement scheduling**

2135 Ozonesondes are classified as ancillary measurements that provide complementary priority 1  
2136 ECV measurements of temperature, pressure and water vapor, and priority 2 ECV measurements  
2137 of ozone in the troposphere and lower stratosphere. All ECC-sensors considered in this report are  
2138 considered to be research-grade instruments. To date, measuring ozone at a fixed high vertical  
2139 resolutions with high precision can only be done by ozonesondes. Thus, it is highly desirable to  
2140 include GRUAN ozonesonde data records to service end-user communities defined in Section 1.2.

2141

2142 Measurement scheduling for GRUAN ozonesondes is driven by one main factor: financial  
2143 support for expendables which include the ozonesonde, interface electronics, and the balloon  
2144 payload. Each ozonesonde is considered a unique instrument and generally, once an ozonesonde  
2145 is launched it is lost. It is not common for sites to retrieve, re-condition, and re-launch the same  
2146 sensor. Geography, land restrictions, weather, and additional resources can prohibit such rescue  
2147 attempts. Schedules will depend upon available expendables and so there cannot be a “one-size  
2148 fits all” solution.

- 2149
- 2150 • In seeking a practical balance between sites with funding constraints and GRUAN
- 2151 scientific goals, **GRUAN shall accept a minimum requirement of two times per**
- 2152 **month launches to be spaced every other week.** Sites seeking to become GRUAN sites
- 2153 shall first be assessed according to their ability to meet the mandatory operating protocols
- 2154 defined in Section 5.3 of GCOS-171 and then according to the added value they bring to
- 2155 the network, as defined in Section 3.2.1.
- 2156 1. A **fully** equipped GRUAN ozonesonde site shall make weekly launches. If and when
- 2157 possible, GRUAN shall encourage candidate or newly certified sites to become a fully
- 2158 equipped GRUAN site.
- 2159 2. Sites shall upload metadata and PRD to the RSLaunchClient as soon as the launch is
- 2160 complete and that site has successfully archived their metadata and PRD.
- 2161 3. Sites shall commit to launching at around the same time of day. This is to maintain the
- 2162 representativeness and homogeneity of the data record. Variable ozonesonde launch
- 2163 times may affect the accuracy of trend assessments [Thompson et al., 2014].
- 2164 4. To the extent possible, ozonesonde launches should be timed to coincide with satellite
- 2165 overpass times that measure total column ozone and/or vertical profiles of ozone.
- 2166 5. Weather permitting, GRUAN advises launching the same day for bi-monthly to weekly
- 2167 sounding schedules. Altering a planned launch date due to inclement weather such as a
- 2168 natural disaster, strong winds, heavy rains, and storms that would impede a successful
- 2169 launch is expected. Altered scheduled launches shall be included as part of the annual
- 2170 report summaries.
- 2171 6. Where possible, measurement schedules for redundant systems should be synchronized
- 2172 so as to avoid sampling biases when combining the measurements into a single data
- 2173 product.

2174

### 2175 **5.3 Raw data acquisition and archiving**

2176 The rawest form of ozonesonde data (PRD) acquired within a certified GRUAN ozonesonde

2177 programme and leading to the production of certified GRUAN data products is subject to all

2178 articles of the GRUAN data management policy described in Section 8 of GCOS-171, and

2179 adapted specifically for the ozonesondes in Section 3.4.

2180

2181 **The ozonesonde PRD acquisition procedure** should follow the optimal SOPs defined in

2182 Section 3.5. The essential raw data and metadata per ozonesonde launch shall then be uploaded

2183 to the RSLaunchClient (See Tables 3.4 and 3.1 for the lists of essential and metadata and PRD,

2184 respectively).

2185

2186 **The raw data (PRD) format** and metadata shall be in ASCII text and the RSLaunchClient shall

2187 be responsible for converting the PRD to Level 1 converted raw data files (CRD) for processing

2188 by the GOASS described in Section 3.7 to create the GRUAN standard product (SGDP).

2189

#### 2190 **Raw data (PRD) sampling**

2191           **Vertical range:** 1-2 second raw data with no averaging.  
2192           **Temporal range:** As defined in Section 5.2 a minimum of bi-weekly launches will be  
2193 accepted, although weekly launches are the ideal and encouraged.  
2194  
2195 GRUAN Ozonesonde Programmes PRD are expected to be archived in perpetuity at the site  
2196 where the measurements took place, and must be uploaded as soon as the launch cycle is  
2197 complete onto the designated centralized GRUAN ozonesonde data handling facility. The upload  
2198 procedure must be performed using the mandatory RSLaunchClient utility. No PRD data shall be  
2199 accepted if they are not uploaded through the RSLaunchClient utility. If one or several changes  
2200 of instrumentation or operating procedure occurred during a given 24 hours cycle, the PRD must  
2201 be uploaded separately for each of the multiple uninterrupted data acquisition periods, each of  
2202 these periods shall be considered as a separate GRUAN ozonesonde observation. Each GRUAN  
2203 Ozonesonde Programme should have included in their certification application a full description  
2204 of the local storing location and an overview of the raw data format.  
2205

## 2206 6 DATA PROCESSING AND UNCERTAINTY BUDGET

2207 The measurement uncertainty of the ozonesonde system describes the current best knowledge of  
2208 instrument performance under the conditions encountered during an observation. This section  
2209 summarizes how the centralized GRUAN Ozonesonde Analysis Software System (*GOASS*)  
2210 processes the raw ozonesonde data (*PRD/CRD*) to produce a GRUAN ozonesonde standard data  
2211 product (*SGDP*).

2212  
2213 The assessment of the uncertainty budget of ozone measured from ozonesondes is a complex  
2214 task. Measurement uncertainties in ozonesondes should, in the first instance, be characterized in  
2215 the laboratory. In the past, JOSIE (Jülich Ozonesonde Inter-comparison Experiment) has played  
2216 a key role in describing/analyzing all sources of measurement uncertainty to the extent possible,  
2217 quantifying/synthesizing the contribution of each source of uncertainty to the total measurement  
2218 uncertainty, and verifying that the derived net uncertainty is a faithful representation of the true  
2219 uncertainty and is in agreement with the required (expected) target uncertainty. However, results  
2220 from laboratory studies should be corroborated with field campaigns which are likely to test the  
2221 sondes in an environment closer to their standard operating environment e.g. the BESOS  
2222 (Balloon Experiment on Standards for Ozonesondes) campaign (Deshler et al., 2008). While it  
2223 may be necessary to GRUAN to conduct laboratory studies and/or field campaigns to resolve  
2224 operational issues specific to the use of ozonesondes within GRUAN, the GRUAN ozonesonde  
2225 community must, wherever possible, collaborate with other international ozonesonde  
2226 communities such as GAW, NDACC and SHADOZ whenever they are conducting laboratory  
2227 studies and/or field campaigns.  
2228

2229 With regards to the BM and CI type sondes it shall be the responsibility of the Lead Centre and  
2230 the WG-GRUAN to evaluate the appropriateness of uncertainty estimates and determine if BM  
2231 and CI data records are of sufficient quality to meet the GRUAN reference measurement  
2232 standards (see Section 8 on Quality Management).

### 2233 6.1 The Ozone uncertainty equation: Principles and rationale

2234 Since the 1990's tests conducted by JOSIE-led experiments, campaigns such as BESOS, and dual  
2235 flight experiments have clearly demonstrated the need to characterize singular features of the  
2236 ECC ozone sensors and standardize measurements. These activities have lead to the creation of  
2237 the ASOPOS panel whose goals are to (i) standardizing the ozonesonde conditioning and  
2238 preparation procedures, (ii) establishing guidelines for the reprocessing and homogenization of  
2239 ozonesonde data records, and (iii) determining the contributions of the individual uncertainties  
2240 of the different instrumental parameters to the ozone measurement. The WMO/GAW Report 201  
2241 is a comprehensive summary of the ASOPOS findings and is the foundation on which GRUAN  
2242 has used to established this technical report. The treatment of uncertainty in the GRUAN  
2243 ozonesonde data processing will follow the recommendations and definitions of the WMO/GAW  
2244 Report 201. These uncertainty parameters are part of the ozonesonde SGPD.

2245  
2246

## 2247 **The Ozone Uncertainty Equation**

2248

2249 GRUAN shall adopt the WMO/GAW ozone uncertainty equation taken from Equation E-3-2 in  
2250 Smit et al, [2014]). It is written as follows:

2251

2252 Eqn. 6.1.1

2253

$$2254 \frac{\Delta P_{O_3}}{P_{O_3}} = \sqrt{\frac{(\Delta I_M)^2 + (\Delta I_B)^2}{(I_M + I_B)^2} + \left(\frac{\Delta \eta_C}{\eta_C}\right)^2 + \left(\frac{\Delta \Phi_P}{\Phi_P}\right)^2 + \left(\frac{\Delta T_P}{T_P}\right)^2 + \left(\frac{\Delta \Psi}{\Psi}\right)^2}$$

2255

2256

2257 where the term,  $\left[\frac{(\Delta I_M)^2 + (\Delta I_B)^2}{(I_M + I_B)^2}\right]$  is the contribution of the uncertainty in  
2258 background current, the  $\left(\frac{\Delta \eta_C}{\eta_C}\right)^2$  term is the contribution of the conversion efficiency  
2259 uncertainty, the  $\left(\frac{\Delta \Phi_P}{\Phi_P}\right)^2$  term is the pump flow rate uncertainty, the  $\left(\frac{\Delta T_P}{T_P}\right)^2$  term is the  
2260 contribution of the pump temperature, and the  $\left(\frac{\Delta \Psi}{\Psi}\right)^2$  term is the pump flow correction factor  
2261 uncertainties. Equation 6.1.1 is the sum of the squares of the uncertainty in each term of the  
2262 ozone partial pressure equation (Section 2.1, Eqn. 1). The uncertainties are assumed to be  
2263 random and gaussian and therefore follow the gaussian law of error propagation. Each  
2264 instrumental uncertainty term is defined in subsequent sections.

## 2265 **6.2 Contribution of the uncertainty in background current**

2266 The term  $\left[\frac{(\Delta I_M)^2 + (\Delta I_B)^2}{(I_M + I_B)^2}\right]$  from equation 6.1.1 is the contribution of the uncertainty  
2267 in background current, where  $\Delta I_M$  is the uncertainty in the measured current,  $I_M$ , and  $\Delta I_B$  is the  
2268 uncertainty in the background current,  $I_B$ .

2269

2270 There is no standard or statistically robust method for estimating the uncertainty of the  
2271 background current. JOSIE experiments used small sample sizes, less than 14 ECC sensors, to  
2272 conduct the background current experiments published in Smit et al, [2007] and ultimately used  
2273 in the WMO/ASOPOS guidelines [Smit et al, 2012; 2014]. Results from Table 7 of Smit et al.  
2274 [2007] record an average  $I_{B0}$  measurement ('background current before  $O_3$ -exposure') and 1-  
2275 sigma uncertainty of  $0.02 \pm 0.02 \mu A$  using ENSCI sensors with a 0.5% half buffer KI solution and  
2276  $0.023 \pm 0.013 \mu A$  using Science Pump Corporation (SPC) sensors with a 1.0% full buffer KI  
2277 solution.

2278

2279 Based on the JOSIE results above, GRUAN will adopt a  $\pm 0.02 \mu A$  background current  
2280 uncertainty,  $\Delta I_B$ , for ENSCI 0.5% half buffer KI solution and a  $\pm 0.013 \mu A$  uncertainty for  
2281 Science Pump ECC 1.0% full buffer KI solution because there are no other uncertainty estimates  
2282 for  $I_{B0}$  in the literature. Furthermore, there is the added complication that this is a single  
2283 measurement per unique ECC sensor so uncertainties cannot be directly ascertained.

2284

2285 The uncertainty in the ozone current,  $\Delta I_M$ , shall be set to 0.1  $\mu\text{A}$  which is the resolution of the  
 2286 digital interface board (Terry Deshler/UWy and Herman Smit/Forchungszentrum, personal  
 2287 communication).

2288  
 2289 The uncertainty constants are summarize in Table 6.2.1 below.

2290  
 2291 Table 6.2.1 Constants in the ozone current uncertainties

ECC Sensor	$\Delta I_M$	$\Delta I_B$
ENSCI/0.5%	$\pm 1\%$ of measured currents above 1 $\mu\text{A}$ , and $\pm 0.01 \mu\text{A}$ for currents below 1 $\mu\text{A}$ .	$\pm 0.02 \mu\text{A}$
SPC/1.0%		$\pm 0.013 \mu\text{A}$

2292  
 2293  
 2294 Background uncertainties outside the ENSCI/0.5% and SCP/1% pairing shall have to undergo  
 2295 similar rigorous testing to establish uncertainty estimates. In this case, profiles shall be stored in  
 2296 CRD format until such time as background uncertainties can be establish and applied to create  
 2297 the ozonesonde SGDP. SGDP cannot be generated unless all uncertainty contributions to ozone  
 2298 in Equation 6.1. are known.  
 2299

### 2300 **6.3 Contribution of the uncertainty in pump flow rate**

2301 From Section 2.4 Equation 2.4.1 the final mean flow rate is corrected for the humidification  
 2302 effect,  $C_{PH}$ , and differences between the internal pump temperature and the ambient air,  $C_{PL}$ .  
 2303

2304 The uncertainty associated with the determination of the mean flow rate is the ratio of the  
 2305 standard deviation of the five flow rates to the square root of the sample population, which in this  
 2306 case is five. The equation is expressed as  
 2307

2308 Equation 6.3.1 
$$\Delta T_{100} = \frac{\sigma_{T100}}{\sqrt{N}} \quad \text{where } N=5$$

2309  
 2310 This equation is based on error analysis by Bevington and Robinson [1992] (Chapters 3 and 4).  
 2311

2312 The uncertainty in  $C_{PH}$  and  $C_{PL}$  are site specific. For existing sites that have established at least  
 2313 one year's worth of ozonesonde launches, i.e. a minimum of 24 total launches, relative  
 2314 uncertainties,  $\Delta C_{PH}$  and  $\Delta C_{PL}$ , shall be calculated in the following way  
 2315

2316 Equation 6.3.2 
$$\Delta C_{PH} = \frac{\sigma_{CPH}}{\sqrt{N_{CPH}}}, \quad \Delta C_{PL} = \frac{\sigma_{CPL}}{\sqrt{N_{CPL}}}$$

2317  
 2318  
 2319 where  $N_{CPH}$  and  $N_{CPL}$  are a minimum of 24 and  $\sigma_{CPH}$  and  $\sigma_{CPL}$  are the 1-sigma standard deviation  
 2320 of the  $C_{PH}$ ,  $C_{PL}$ , respectively, as defined in Section 2.4.  
 2321

2322 For new GRUAN Ozonesonde Programmes with no launch history it is impossible to estimate  
 2323  $\Delta C_{PH}$  and  $\Delta C_{PL}$ . In this case, the term shall not be used in the ozone uncertainty equation until  
 2324 after one years worth of ozonesonde launches have been processed by the GRUAN Lead Centre.  
 2325 Until such time, profiles shall be stored in CRD format until  $\Delta C_{PH}$  and  $\Delta C_{PL}$  can be calculated and  
 2326 then used to create the ozonesonde SGDP.  
 2327

2328 Table 6.3.1 Uncertainty estimates for the pump flow rate

$\Delta T_{100}$	Use Equation 6.3.1
$\Delta C_{PL}$	Use Equation 6.3.2
$\Delta C_{PH}$	Use Equation 6.3.2

2329  
 2330 Thus, the full equation to calculate the pump flow rate uncertainty shall be expressed in the  
 2331 following equation  
 2332

2333 Equation 6.3.3 
$$\frac{\Delta \Phi_p}{\Phi_p} = \sqrt{\left(\frac{\Delta T_{100}}{T_{100}}\right)^2 + (\Delta C_{PL})^2 + (\Delta C_{PH})^2}$$

2334  
 2335 This term may change as the data record expands, thus  $\Delta C_{PH}$  and  $\Delta C_{PL}$  should be continually  
 2336 evaluated by the Ozonesonde Programmes annually to check for large deviations from its  
 2337 constant value and assess whether and how fluctuations in the uncertainty terms affect the ozone  
 2338 uncertainty significantly. It may be that re-processing of the entire data record of a given site is  
 2339 required if  $\Delta C_{PH}$  and  $\Delta C_{PL}$  statistics changes significantly over time.  
 2340

## 2341 **6.4 Contribution of the uncertainty in pump correction factor (PCF)**

2342  
 2343 The uncertainty in the pump correction factors (PCF),  $\Delta \Psi$ , shall be taken from Table 2.5.1 and  
 2344 are re-iterated in Table 6.4.1 below.  
 2345

2346 Table 6.4.1 Pump correction factor uncertainties

2347

Pressure [hPa]	K86 $\Delta \Psi$	K95 $\Delta \Psi$
Sfc-100	0.000	0.000
100	0.005	0.005
50	0.006	0.005
30	0.008	0.008
20	0.009	0.012
10	0.010	0.023
7	0.012	0.024
5	0.014	0.024

3	0.025	0.043
---	-------	-------

2348

2349 Calculating  $\Delta\Psi$  between data points shall be done on a log pressure scale with polynomial  
 2350 interpolation.

2351

2352 From Table 6.4.1 the GRUAN GOASS shall use the following PCF uncertainties to the  
 2353 following ECC sensors:

2354 (i) K86  $\Delta\Psi$  for SPC ECCs

2355 (ii) K95  $\Delta\Psi$  for ENSCI ECCs.

2356

2357 New ECC sensors shall have to undergo similar JOSIE testing, laboratory and field tests to  
 2358 establish and validate their PCF values and uncertainties. GRUAN protocols for managing a  
 2359 change in sensor technology shall follow guidelines put forth in Section 7.1.

2360

## 2361 6.5 Contribution of the uncertainty in pump temperature

2362

2363 Calculating the adjusted pump temperature is discussed in detail in Section 2.6 and the  
 2364 associated uncertainties are summarized in Table 6.5.1 below.

2365

2366 Table 6.5.1 Uncertainties based on the location of the pump temperature thermister.

Case	Location	Sonde Type	$\Delta T_P$	$\Delta T_{PCase}$	$\Delta T_{Piston-internal}$
1	Bottom of circuit board	SPC 2A, 3A, 4A	$\pm 1.0K$	$\pm 1.0K$	$\pm 0.5K$
2	Suspended in the styrofoam box in the vicinity of the pump	SPC 5A	$\pm 0.5K$	3.9–1.13Log <sub>10</sub> (P) for P > 70hPa 3.0–1.13Log <sub>10</sub> (P) for P ≤ 70 hPa	$\pm 0.5K$
3	Taped thermister at the pump base	SPC 5A	$\pm 0.5K$	Same as Case 2	$\pm 0.5K$
4	Epoxied at the pump base	SPC 5A	$\pm 0.5K$	$\pm 0.5K$	$\pm 0.5K$
5	Mounted inside the pump body, close to the piston	EnSci Z & 2Z, SPC 6A	$\pm 0.5K$	No uncertainty	$\pm 0.5K$

2367

2368 The additional correction to account for differences between moving piston,  $T_{piston}$ , and the  
 2369 internal pump, or pump based, temperatures is defined as  $\Delta T_{piston-internal} = \pm 0.5K$  and is true for all  
 2370 cases.

2371

2372 The full contribution of the measured pump temperature to the ozone uncertainty includes the  
 2373 uncertainty of the additional corrections defined in Section 2.6 and summarized in Table 6.5.1.

2374 This equation is expressed as

2375

2376 Equation 6.5.1 
$$\frac{\Delta T_p}{T_p} = \sqrt{\left(\frac{\Delta T_p}{T_p}\right)^2 + \left(\frac{\Delta T_{pCase\_i}}{T_p}\right)^2 + \left(\frac{\Delta T_{piston-int\ ernl}}{T_p}\right)^2}$$

2377

2378

### 2379 **6.6 Contribution of the uncertainty in the conversion efficiency**

2380 GRUAN shall adopt the WMO/GAW uncertainty calculation for the conversion efficiency [Smit  
2381 et al., 2014, Equation E-3-4], written as

2382

2383 Equation 6.6.1 
$$\frac{\Delta \eta_c}{\eta_c} = \sqrt{\left(\frac{\Delta \alpha_{O_3}}{\alpha_{O_3}}\right)^2 + \left(\frac{\Delta S_{O_3:I_2}}{S_{O_3:I_2}}\right)^2}$$
 where,

2384

2385  $\Delta \eta_c / \eta_c$  = conversion efficiency uncertainty term to be used in the ozone uncertainty equation  
2386 6.1.1

2387  $\alpha_{O_3}$  = absorption efficiency from the gas into liquid phase of the sensing solution = 1.0

2388  $\Delta \alpha_{O_3}$  =  $\alpha_{O_3}$  uncertainty =  $\pm 0.01$

2389  $S_{O_3:I_2}$  = stoichiometry of the conversion of  $O_3$  to  $I_2$  = 1.0

2390  $\Delta S_{O_3:I_2}$  =  $S_{O_3:I_2}$  uncertainty =  $\pm 0.02$  at  $Z=0$ km with a linear increase to  $\pm 0.05$  at  $Z=35$ km. This  
2391 translates to the linear equation,

2392

2393 Equation 6.6.2 
$$\Delta S_{O_3:I_2}(Z) = 0.000857143 * Z + 0.02$$

2394

2395 Setting the absorption efficiency ( $\alpha_{O_3}$ ) equal to one are for cases where the volume of the cathode  
2396 solution is  $3.0 \text{ cm}^3$ . GRUAN will use the following WMO/GAW equations to calculate  $\alpha_{O_3}$  for a  
2397  $2.5 \text{ cm}^3$  volume, as follows

2398

2399 Equation 6.6.3 
$$\alpha_{O_3}(P) = 1.0044 - 4.4 \times 10^{-5} * P \quad 100 \text{ hPa} < P < 1050 \text{ hPa}$$

2400 Equation 6.6.4 
$$\alpha_{O_3}(P) = 1.0 \quad P \leq 100 \text{ hPa}$$

2401

2402  $\Delta \alpha_{O_3}$  is  $\pm 0.01$  for both cathode volumes.

2403

2404 GRUAN shall require new candidate sites to use  $3.0 \text{ cm}^3$  volume cathode sensing solution to  
2405 reduce added uncertainty in the ozone uncertainty equation and maintain a constant absorption  
2406 efficiency throughout the profile measurements.

2407

### 2408 **6.7 Contribution of the uncertainty in the radiosonde temperature and** 2409 **pressure to ozone uncertainty**

2410 The designated GRUAN Ozonesonde Lead Centre shall adopt the GRUAN Radiosonde  
2411 Technical Report (X.X.X) processing procedures for calculating the uncertainties associated with  
2412 the radiosonde measurements. Handling biases in the geopotential height calculation in the

2413 absence of GPS measurements shall be the responsibility of the Radiosonde WG-GRUAN,  
2414 assigned task team, and responsible Lead Centre.

## 2415 **7 MANAGING CHANGES**

2416 Changes in instrumentation, operating procedures, and data processing algorithms are likely to  
2417 introduce sources of operational uncertainty into the ozone profiles measured within GRUAN  
2418 Ozonesonde Programmes. The primary goals are to (i) avoid unnecessary changes, i.e. those  
2419 changes that have no scientific, financial or operational benefit, and (ii) where changes are  
2420 beneficial and/or necessary, to manage those changes in a way that the homogeneity of the  
2421 ozonesonde data record is maintained across the transition and that the change does not  
2422 compromise the integrity of the long-term record.

2423  
2424 Ozonesonde have gone through several modifications since they were first introduced in the  
2425 1960's and there is no reason to believe that those modifications will cease. Without such  
2426 modifications there would be no opportunity to improve the performance of the instruments.  
2427 Therefore, while GRUAN encourages ozonesonde manufacturers to improve the performance of  
2428 the instruments, GRUAN also recognizes that managing such changes in instrument design or  
2429 function is essential for determining long-term stability of the ozonesonde data products.

2430  
2431 Factors influencing trends in an ozonesonde dataset to consider include the following changes  
2432 (termed as “9 items” hereinafter):

- 2433
- 2434 1. SOPs
  - 2435 2. GOASS data processing algorithms
  - 2436 3. ECC-sensor manufacturer
  - 2437 4. Solution concentration
  - 2438 5. Location of launch site
  - 2439 6. Operating environment of the ozonesonde
  - 2440 7. Ground station system
  - 2441 8. Radiosonde manufacturer
  - 2442 9. Including refurbished ECC-sensors

2443  
2444 They are all likely to introduce inhomogeneities into ozonesonde SGDP. This section describes  
2445 the protocols for managing changes in the ozonesonde SGDP. This section is developed based on  
2446 the section “Managing change” of the GCOS-171 GRUAN Guideline.

### 2448 **7.1 Guiding principles**

2449 The GCOS climate monitoring principles relevant to guiding principles for managing changes in  
2450 GRUAN Ozonesonde Programme include:

- 2451
- 2452 • The impact of new ozonesonde systems or changes to existing systems should be  
2453 assessed prior to implementation.
  - 2454 • A suitable period of overlap for new and old items is required. This will be dictated  
2455 by the GCOS-171 guidelines and is addressed further in Section 7.7.

- 2456 • *Embracing change:* GRUAN Ozonesonde Programmes must not be resistant to  
2457 change but must actively encourage carefully managed changes. However, the  
2458 advantages of making any change must always be weighed against the inherent  
2459 disadvantages of making a change.
- 2460 • *Change event notification:* A change event begins with the start of change of any one  
2461 of the above “9 items”.
- 2462 • A change event notification is first issued by the GRUAN site by email to the  
2463 GRUAN Lead Centre.
- 2464 • The Lead Centre, a GRUAN Ozonesonde Programme, an ozonesonde instrument  
2465 manufacturer, or another member of the GRUAN community can initiate a proposal  
2466 for changes.
- 2467 • A change event ends with the official acceptance of the change that has been made  
2468 after a careful and rigorous assessment. Proposed changes in (1) and (2) of the “9  
2469 items” will likely be initiated by the Lead Centre.
- 2470 • *Justification of change:* Any change to the “9 items” above in a GRUAN Ozonesonde  
2471 Programme must be fully justified before the change is enacted. An assessment report  
2472 must be submitted in which advantages and disadvantages of making the change must  
2473 be carefully assessed. Laboratory tests of old and new items (anyone of the “9 items”  
2474 listed above) should be included in the assessment report.
- 2475 • The Lead Centre must act as a clearinghouse for all proposed changes to (a) assure  
2476 high stability and (b) decide when an improvement merits a change to the GRUAN  
2477 ozonesonde procedures.
- 2478 ◦ The Lead Centre, in consultation with ozonesonde experts, makes an initial  
2479 evaluation of the proposed change.
- 2480 ◦ If considered to be worth pursuing, the Lead Centre assesses the advantages,  
2481 disadvantages, and potential impacts of the proposed change.
- 2482 • The information and data required to manage the change are captured in a “change  
2483 evaluation report” that will become a key component of the metadata associated with  
2484 the change.
- 2485 • *Preparing for change:* A quantitative assessment of the impacts of any planned  
2486 change must be undertaken before the implementation of the change.
- 2487 • The assessment must cover a sufficient period of time, not just covering the change  
2488 period.
- 2489 ◦ If the knowledge needed for quantitatively assessing the impact of changes exists, it  
2490 should be immediately encapsulated in the metadata associated with the change event.  
2491 Official acceptance of the change should be expedited so that there is no disruption to  
2492 the launch schedule.
- 2493 ◦ Some changes have already been anticipated and assessed in this Document with a  
2494 change implementation process as part of the GOASS (e.g. changing from SPC to

- 2495 ENSCI, or changing solution strength (See Section 7.2)). In this case, official  
 2496 acceptance of the change should be expedited so that there is no disruption to the  
 2497 launch schedule.
- 2498 ◦ If additional laboratory studies or dual ozonesonde launches are required, such studies  
 2499 must be undertaken by either the Lead Centre, a task force commissioned by the Lead  
 2500 Centre, the GRUAN site scientists, members of the ASOPOS panel, or other  
 2501 ozonesonde experts. Any relevant results in the peer-reviewed literature should be  
 2502 included in any change assessment.
- 2503 • The impact on the ozonesonde SGDP product and its uncertainty needs to be assessed in  
 2504 such a way that (1) knowledge of the newly changed item is at least as detailed as  
 2505 knowledge of the old one, (2) tests are, or have been, conducted (e.g. processing a large  
 2506 number of common datasets by both new and old algorithms if a change in algorithm is  
 2507 proposed), (3) the resulting ozonesonde SGDP after the change are either unchanged or  
 2508 an improvement to those prior to change, in terms of continuity, accuracy or integrity. If  
 2509 continuity, accuracy and integrity cannot be improved at the same time, at least they  
 2510 should not be worse than before. If a considerable improvement in one aspect (e.g.  
 2511 accuracy) is gained, at the cost of a slight degradation of the other aspects, it might be  
 2512 still justifiable to propose a change.
- 2513 • When laboratory studies and dual ozonesonde launches are proposed to be conducted,  
 2514 regular observations schedule must not be interrupted. In the case when laboratory or  
 2515 field studies cannot be reconciled, this must be noted as part of the metadata. In this case,  
 2516 a proposal of how to resolve the discrepancy should be developed by the Lead Centre  
 2517 WG-GRUAN.
- 2518 • If the GRUAN site decides to proceed and implement the change, any data and metadata  
 2519 collected as part of the change process, as well as a full report on how the change is  
 2520 managed and implemented, must be submitted to the Lead Centre within 3 months of the  
 2521 completion of the change. This information will then be archived as part of the metadata  
 2522 record for the ozonesonde data series from that GRUAN site.
- 2523 • *Validating impacts:* No discontinuities in the measurement series should occur if a  
 2524 change has been properly managed. This is done through the *justification* (5) and  
 2525 *preparing for change* (6) items. Validation of the process can be achieved by  
 2526 subjecting the entire measurement series to homogenization tests, or may require a  
 2527 reprocessing of historical data. Impacts of changes must be assessed in light of the  
 2528 different intended uses of GRUAN ozonesonde data products.
- 2529 • *Change and uncertainty:* Knowledge of an ozonesonde measurement system can  
 2530 never be complete or perfect. Transitioning from an old to a new measurement system  
 2531 always introduces an additional source of uncertainty which must be captured in the  
 2532 uncertainty estimate on the measurements.
- 2533 • *Supporting reprocessing:* As new and more in-depth knowledge of ozonesonde  
 2534 instrumentation and processing is gained, and in particular following change events  
 2535 (see #4), reprocessing of historical data may be necessary. Such reprocessing may  
 2536 require revision of the homogenization procedures applied at each previous change

2537 event to produce a homogenized data record. It is essential, therefore, that raw data,  
2538 as was well as detailed metadata collected during change events, are archived so that  
2539 such reprocessing can be easily achieved.

- 2540 • *Single changes*: Whenever a measurement system is changed, as many similarities as  
2541 possible between the old and new systems should be maintained e.g. both the  
2542 ozonesonde and ground-station should not be simultaneously changed. Multiple  
2543 simultaneous changes must be avoided so that the quantitative assessment of the  
2544 impact of the change on the measurement and its uncertainty is not confounded with  
2545 other, simultaneous, assessments.
- 2546 • *Monitoring changes*: Most changes are planned and therefore can be managed.  
2547 However, some changes may be unplanned (e.g. natural disaster, changes in funding).  
2548 Under these circumstances, GRUAN sites shall be placed on hold until the site can be  
2549 re-established. It may be that re-certification is required. This shall be determined by  
2550 a site visit from members of the Lead Centre (see Section 3.2).
- 2551 • *Use of independent, redundant measurements*: Redundancy in ozone measurement  
2552 systems provides a powerful tool for validating the management of changes in any  
2553 one of those systems. To take advantage of measurement system redundancy, it is  
2554 essential that these independent systems are not changed simultaneously.
- 2555 • *Use of models*: Where changes in an historical measurement record have not been  
2556 adequately managed, and where physical or statistical models can faithfully  
2557 reproduce the key characteristics of the measurement record, the model time series  
2558 can provide a means of detecting and correcting for systematic biases between old  
2559 and new measurement systems. In GRUAN, where all changes are managed changes,  
2560 the use of models for this purpose should not be necessary.
- 2561 • *Manufacturer involvement*: Efforts must be undertaken to avoid unknown changes  
2562 e.g. the instrument manufacturer making unannounced changes. GRUAN needs to  
2563 establish close working relationships with instrument manufacturers so that any  
2564 changes implemented in the manufacturing of an instrument are made know to the  
2565 GRUAN ozonesonde community.

2566

## 2567 7.2 Transfer Functions

2568 There have been a number of studies that have used laboratory, dual-sonde, and multi-sonde  
2569 payloads to derive methods of calculating transfer functions that characterize differences in  
2570 instrument and solution concentration [Smit et al., 2007; Kivi et al., 2007; Deshler et al., 2008;  
2571 Stubi et al., 2008; Mercer et al., 2008].

2572  
2573 As part of the SPARC-IGACO-IOC-NDACC (SI2N) initiative, the Assessment of Standard  
2574 Operating Procedures for Ozone Sondes (ASOPOS) working group established empirical  
2575 transfer functions specifically for the SPC and ENSCI type ozonesondes using either the 1% full  
2576 buffer or 0.5% half buffer solutions [Smit et al., 2012]. This work uses all data taken from the  
2577 above cited studies. Their aim is to homogenize long term ozonesonde records, that use these

2578 sensor/solution combinations, for ozone assessments of changes in the vertical distribution of  
2579 ozone [<http://igaco-o3.fmi.fi/VDO/documents.html>].

2580  
2581 These transfer functions represent the quantitative differences of the ozonesonde response based  
2582 on changes in instrumentation and stoichiometry of the conversion of O<sub>3</sub> to I<sub>2</sub> with a change in  
2583 solution concentration. They are not a reflection of changes in SOPs. Smit et al. [2007] and  
2584 Thompson et al. [2007] showed that there are discontinuities in the time series of a single site  
2585 that have used a variety of instruments and solution strength, citing the need to homogenize the  
2586 long term records of individual ozonesonde sites.

2587  
2588 The conversion relationship is summarized in Table 3 of Smit et al. [2012].

### 2589 **GRUAN processing protocol**

- 2590  
2591  
2592 1. Where applicable, transfer functions taken from Smit et al. [2012] shall be applied and  
2593 shall be part of the ozonesonde SGDP.
- 2594  
2595 2. Data records where transfer functions should be applied but do not yet exist shall remain  
in the Level 2 stage but shall not be considered as part of the ozonesonde SGDP.
- 2596  
2597 3. Transfer functions for time series that use a combination of BM and ECC shall follow  
2598 WMO/GAW #201 Report guidelines found in Section 4.3 and subsections. It shall be the  
2599 responsibility of the Lead Centre and the WG-GRUAN to evaluate the appropriateness of  
2600 the transfer functions and determine if BM data records are of sufficient quality to meet  
the GRUAN reference measurement standards.
- 2601  
2602 4. As of this document, there are no transfer functions for time series that use a combination  
2603 of CI and ECC sondes. However, dual sonde launches have been conducted by Nakamura  
2604 et al., [2008] and have the potential to be used to develop transfer functions. The Lead  
2605 Centre and WG-GRUAN shall work with the manufacturer (Japanese Meteorological  
2606 Agency) to determine the extent to which uncertainties estimates have been established  
2607 and validated and the status of deriving transfer functions between CI and ECC sondes by  
2608 the group. It shall be the responsibility of the Lead Centre and the WG-GRUAN to  
2609 evaluate the appropriateness of the transfer functions and determine if the historic CI data  
2610 records are of sufficient quality to meet the GRUAN reference measurement standards.

### 2611 **7.3 Managing changes in instrumentation**

2612 GRUAN Ozonesonde Programme is characterized by the fact that every ozone profile is  
2613 measured with a different instrument. Managing changes in instrumentation therefore extends to  
2614 managing changes in sondes between flights. Efforts must be undertaken to avoid unknown  
2615 changes e.g. the instrument manufacturer making unannounced changes to the material or  
2616 configuration of the ECC sensor, or a ground station software update. Late response to changes  
2617 or upgrade announcements may result in discrepancies in the measurement time series. One way  
2618 to ensure that instrument changes are identified, characterized, and recorded such that there is no  
2619 discontinuity in the network, as a whole, is for mandatory GRUAN representation at future

2620 JOSIE studies. This will not only safeguard the homogeneity of datasets due to instrumentation  
2621 changes but will also ensure that GRUAN:

2622

2623 1. Follows retractions or addendum's to the original GAW Report No. 201  
2624 recommendations and SOP protocols.

2625 2. Be informed of changes in manufacturer design and materials, and how these affect  
2626 ozonesonde performance.

2627 3. Be aware of changes in the processing software.

2628 4. Be advised of additional concerns in the SOPs.

2629

2630 All of the above will impact GRUAN processing procedures. Therefore, GRUAN participation  
2631 should be mandatory.

2632

2633 GRUAN Lead Centre needs to establish close working relationships with ozonesonde instrument  
2634 manufacturers (e.g. SPC and ENSCI) and ozonesonde/radiosonde ground station manufacturers  
2635 (e.g. Vaisala, Modem, Chang Feng, etc) so that any changes to be implemented or having been  
2636 implemented are known to them. Preferably the changes can be known substantially in advance  
2637 of deployment, allowing sufficient time to investigate, understand, prepare for and document the  
2638 change and its likely impacts. Links to instrument manufacturers: Dealing with changes in  
2639 instrumentation will require GRUAN task team to establish close two-way links to instrument  
2640 and ground station manufacturers. Inclusion of ASOPOS panel members, other ozonesonde  
2641 experts, and other ozonesonde archives (e.g. SHADOZ and NDACC) in discussions of  
2642 instrument change would be advantageous.

#### 2643 **7.4 Managing changes in SOP and operating environment**

2644 Currently, there are multiple variations in ozonesonde preparation procedures since the first  
2645 manual was written [Komhyr, 1986]. Besides modifications in the manufacturer's instructions in  
2646 past the decades, scientific institutions have established their own modified operating  
2647 procedures. There is also a number of ozonesonde processing software that applies their own  
2648 treatment of the variables that go into Equation 1. Testing of the ozonesondes under laboratory  
2649 conditions has showed the need to standardize the operating procedures and provide guidelines  
2650 to homogenize the data based on community consensus [Smit et al., 2014]. Smit et al., [2007]  
2651 reports that maintaining SOPs improves the precision of the overall measurements better than  
2652  $\pm 3-5\%$ . GRUAN recommends that each station maintain the GRUAN Lead Centre certified set  
2653 SOPs for pre-flight and day of flight conditioning established by WMO/GAW to ensure  
2654 consistency and homogeneity in operating practices. The goal here is not to disrupt the continuity  
2655 of the long-term practices.

2656

2657 As described in Section 3.5, while implementing these SOPs is not mandatory, sites are required  
2658 to document where they have deviated from the GRUAN certified SOPs and, when audited, are  
2659 assessed for their ability and willingness to adhere to the SOPs within GRUAN.

2660 Some changes in the operating environment may be unplanned, such as in the event of a natural  
2661 disaster, erosion of the field site or land-use changes that necessitates moving the operating  
2662 environment. Under these circumstances, a GRUAN site shall be placed on hold until the

2663 physical site can be re-established. It may be that the new location is far enough away from the  
2664 original location that a new GRUAN site needs to be established in place of the old site. This  
2665 shall be determined by the task team assigned by the Lead Centre. In this case, re-certification  
2666 will be required because the new location and operating conditions will need to be re-assessed.  
2667 The process of re-certification shall follow the guidelines addressed in Section 3.2.

2668 In their annual report, each site shall document any changes to their current certified SOPs and  
2669 operating environment and include (1) why those changes occurred, (2) how those changes were  
2670 managed, and (3) the impact, if any, on the homogeneity, accuracy, and integrity of their  
2671 measurements.

2672  
2673 GRUAN sites shall follow the change protocol outlined in Section 7.1 if changes to items (1) and  
2674 (6) of the “9 items” occur.

2675  
2676 GRUAN representation at future JOSIE studies is strongly recommended to follow (1)  
2677 retractions or addendum's to the original WMO/GAW Report No. 201, (2) recommendations and  
2678 SOP protocols, and (3) be advised of additional concerns in the SOPs.

## 2679 7.5 Managing changes in data processing algorithms

2680 As in any data processing situation, there will be occasional re-processing of the ozonesonde  
2681 converted raw data (CRD) after updates/upgrades of the GRUAN GOASS, addressed in Section  
2682 3.7. The GOASS must be transparent, i.e., developed and optimized in consultation with WG-  
2683 GRUAN members. WG-GRUAN shall meet regularly to discuss the implementation of updates  
2684 to the GOASS, whether they pertain to one site or the entire ozonesonde network. Planned  
2685 changes in data processing algorithms should be dealt with in a fashion similar to planned  
2686 changes in SOPs (Section 7.4).

2687  
2688 Changes in the GOASS may be due to the following:

- 2689 1. New or modified transfer functions (Section 7.2)
- 2690 2. Updated uncertainty calculations (Section 6)
- 2691 3. Changes in the pump efficiency factors (Section 2.5)
- 2692 4. Changes in the partial ozone column calculation above balloon burst (Section 2.7)
- 2693 5. Changes in the Metadata (Section 3.6)

2694  
2695 Changes resulting in (2) – (5) will likely result in the complete reprocessing of entire data sets  
2696 across the network. Since there is a time and administrative cost associated with the reprocessing  
2697 of a record, such reprocessing should only be undertaken when justified. Protocols must be  
2698 established by the designated Lead Centre ozonesonde data processing facility to indicate when  
2699 reprocessing of the full measurement record at any site is justified or required.

2700  
2701 Traceability is a leading component of GRUAN. Every single GOASS update must be associated  
2702 with an increment of the data processing version. A system of traceable version numbers for all  
2703 ozonesonde level products has been developed to allow for a full identification and tracking of  
2704 the data processing changes made since the initial product delivery. This product versioning  
2705 system shall be determined by the Lead Centre task team.

2706

2707 Data processing updates must be communicated to users who have accessed earlier versions of  
2708 the data and who have voluntarily registered to receive notifications of such data updates (see  
2709 Section 8.6 of the GRUAN Guide). Therefore, all older product versions must be made available  
2710 through the GRUAN archives.

2711

## 2712 7.6 **Managing changes in calibration**

2713 When ozonesondes are calibrated to fundamental calibration standards as part of the pre-flight  
2714 ground-check, changes in sonde performance can be more easily managed. If possible, the  
2715 impacts of a change in calibration should be quantified through traceability of the calibration  
2716 standard. For example, the WCFOS in JOSIE studies satisfies the protocols for maintaining  
2717 ozonesonde continuity, accuracy and integrity through periodic quality checks of instrumental  
2718 performance of ozonesonde from different manufacturers, and establishing up-to-date SOPs.  
2719 It would ideal to establish guidelines by which a GRUAN Ozonesonde Programme can calibrate  
2720 its ground station equipment such that sources of error and uncertainty can be further identified,  
2721 traced, and included as part of the uncertainty budget for ozonesondes. Metadata provides a  
2722 traceable source from which a change in the essential characteristics of each unique ozonesonde  
2723 sensor can be identified, measured, and recorded (essential metadata are addressed in Section  
2724 3.6).

## 2725 7.7 **Validating changes using parallel observations**

2726 Cases where parallel observations are applicable to the ozonesonde programme are the following  
2727 (hereafter called “4 cases”):

- 2728
- 2729 • A new ECC sensor is developed
- 2730 • A new sensing solution recipe is developed
- 2731 • Change in SOPs
- 2732 • Change in radiosonde manufacturer and/or model
- 2733

2734 If any of the above changes occur, a combination of JOSIE studies, other laboratory inter-  
2735 comparisons, and dual sonde launches must be made to establish (1) new precision and accuracy  
2736 estimates, if any, (2) changes in uncertainties, and (3) new transfer functions to maintain  
2737 homogeneity within a time series of a single site and within the network. While these studies are  
2738 proposed and conducted, the regular observations schedule must not be interrupted. In the case  
2739 when laboratory studies cannot be reconciled, this must be noted as part of the metadata. In this  
2740 case, a proposal of how to resolve the discrepancy should be developed by the Lead Centre or a  
2741 task force commissioned by the Lead Centre.

2742

2743 *Measurement redundancy:* Measurement redundancy (see Section 6.2 of GCOS-171) highlights  
2744 the benefits for managing instrumentation change. If parallel observations of the above four  
2745 changes are not feasible, the availability of additional redundant measurements with similar  
2746 sampling attributes (vertical resolution, temporal sampling frequency etc.) is essential for  
2747 validating a managed change. In such cases, an evaluation of the redundant system(s) with the  
2748 old and new systems over an overlap period of at least 12-months must be undertaken to validate  
2749 the robustness of change management.

2750

2751 *Inter-comparisons:* Formal measurement inter-comparisons, in the form of dual ozonesonde  
2752 launches are essential for developing the in depth understanding required to manage changes in  
2753 the “four cases”. For this reason, participation in inter-comparisons is expected. Outcomes from

2754 such inter-comparisons must form an important component of the metadata archived at the  
2755 GRUAN Lead Centre. GRUAN Ozonesonde Programme should participate in, or leverage from  
2756 WMO and partner networks (e.g. SHADOZ and NDACC) instrument inter-comparison  
2757 campaigns.

2758

## 2759 **7.8 Implementation of Network-wide changes**

2760 Considering the critical importance of change management and that GRUAN sites must not act  
2761 unilaterally in implementing changes, a procedure for implementing network-wide changes has  
2762 been described in Section 2.3.11 of the GRUAN Guide to Operations.

2763 Managing change is essential to maintaining network homogeneity. Changes in ozonesonde  
2764 measurement systems, i.e. the “9 items”, at GRUAN sites should therefore be conducted in such  
2765 a way that the homogeneity of the resultant GRUAN ozone data products across the network is  
2766 not compromised. The Lead Centre shall play a key role in ensuring such smooth transitions. In  
2767 particular changes in (1) and (2) of the “9 items” will require network-side changes to ensure  
2768 homogeneity.

2769  
2770 The Lead Centre should consult with ozonesonde experts (e.g. members of the ASOPOS panel),  
2771 science experts from the four key user communities, and other ozonesonde archive centres such  
2772 as SHADOZ and NDACC to thoroughly evaluate the potential implications of network wide  
2773 implementation of the proposed change. If the proposed change is approved, the Lead Centre, in  
2774 consultation with the nominated central processing facility, will develop a formal change plan for  
2775 implementation across the network. The formal change plan is then communicated to all  
2776 GRUAN ozonesonde sites within the network. Any changes or deviations from the documented  
2777 approvals must be considered a new change and must be reassessed by the Lead Centre.  
2778

2779 However, changes are not necessarily always network-wide. In some circumstances, changes to  
2780 an individual site are allowed which do not compromise network homogeneity, for instance  
2781 changes in instrument or solution concentration, a change in instrument operators, or change of  
2782 operating environment. Documentation of these site changes in the form of metadata is essential.  
2783 Sites will be audited on the completeness of their metadata submitted to GRUAN archives as  
2784 part of the site assessment and certification process. Also see #9 in Section 7.1 *Supporting*  
2785 *reprocessing*.

## 2786 **7.9 Data and metadata traceability**

2787 It is essential that metadata associated with the site and each ozonesonde instrument launched,  
2788 and in particular change events (see Section 7.1) that may cause discontinuities in the  
2789 measurement time series, are captured. Sufficient metadata must be available to tie the new  
2790 SGDP via a comparable traceability chain, back to the same recognized standard as the old  
2791 SGDP.

2792  
2793 *Storage:* It is essential that a secondary back-up storage of raw data (L0 PRD) be maintained at  
2794 each GRUAN site. Metadata on written on check lists should be digitized and stored similarly  
2795 with the raw data. Each sites data storage policy shall be evaluated by the WG-GRUAN as part  
2796 of the site assessment and certification process (Section 3.2), and re-evaluated in audits and  
2797 annual reports.  
2798

2799 *Launch scheduling:* Measurement scheduling shall remain stable unless there is a clear  
2800 requirement for change. Amendments to the GRUAN measurement scheduling protocol shall be  
2801 submitted by the WG-GRUAN before being distributed to GRUAN sites for implementation. In  
2802 recognition of the heterogeneity of the network, the scheduling protocols defined in this  
2803 Document may not apply at every GRUAN site, but any deviation from the measurement  
2804 schedule must be agreed by the GRUAN Lead centre and then accepted by WG-GRUAN.  
2805

2806 *Metadata changes from the GRUAN check list:* As described in Section 3.6, while using the  
2807 GRUAN check list is not mandatory, sites are required to document where they have deviated  
2808 from the prescribed check list and, when audited, are assessed for their ability and willingness to  
2809 adhere to them within GRUAN.  
2810

2811 *Importance of Metadata:* Metadata is a critical component when documenting network changes.  
2812 Complete metadata should include a full account of the ozonesonde operation from the time the  
2813 sensor is taken out of its' box to the time of launch release. Detailed archiving of instrument  
2814 metadata will be vital to managing changes in instrumentation. This will allow later reprocessing  
2815 of the raw data as thoroughly as possible (see Section 2.3.4 of GCOS-171). A detailed  
2816 description of how each change in a measurement system was managed can be found in the  
2817 GRUAN check list (Appendix A-1) and a complete list of the essential metadata components is  
2818 in Section 3.6. These metadata lists include everything related to the quantitative assessment of  
2819 the impact of the change on the measurement and its uncertainty.  
2820  
2821

## 2822 8 QUALITY MANAGEMENT

2823 This section defines the principles and the methodological framework for GRUAN operations,  
2824 and details how activities will be coordinated to manage and control data quality within  
2825 GRUAN. This section draws heavily from Section 10 of GCOS-171 and reiterates much of the  
2826 data management policies central to all GRUAN measurement programmes.

2827  
2828 Quality management within GRUAN consists of quality assurance and quality control:

2829  
2830 *Quality assurance (QA)*: The purpose of quality assurance is to provide confidence that the  
2831 requirements for achieving quality will be fulfilled. QA includes all the planned and systematic  
2832 activities that will be implemented such that quality requirements for a product or service will be  
2833 fulfilled.

2834  
2835 *Quality control (QC)*: The purpose of quality control is to ensure that the expectations created by  
2836 QA are fulfilled. QC is associated with those operational methods, techniques and activities used  
2837 to ensure that the quality requirements (as defined by QA) are fulfilled.

2838  
2839 The GRUAN quality management policy is to achieve a level of data quality that allows the  
2840 primary goals of GRUAN to be met for all potential users of GRUAN data products. Quality  
2841 assurance i.e. implementing systems to ensure quality, and quality control i.e. monitoring the  
2842 results to ensure that the systems implemented are adequate to the task, are both required at all  
2843 stages of the GRUAN ozonesonde data production. Because GRUAN ozonesonde data products  
2844 are intended to be used for long-term trend detection, quality assurance and control are further  
2845 extended to data re-processing and to the management of long-term consistency and stability  
2846 (addressed in Section 7 of this Document).

2847  
2848 Methods by which QA for Ozonesonde Programmes can be achieve is through the following:

- 2849
- 2850 1. The use of redundant measurements, as described in Section 4.1.2, serves to assure the  
2851 quality of the GRUAN data products. Agreement of two independent measurements (e.g.  
2852 Lidar and Microwave Radiometer), preferably based on different measurement  
2853 principles, provides a high degree of confidence that no significant systematic effect was  
2854 disregarded and uncertainties were not under-estimated.
  - 2855 2. Laboratory tests are fundamental methods for establishing and confirming uncertainty  
2856 estimates and transfer functions for GRUAN data products. Laboratory tests provide an  
2857 opportunity to investigate in detail the performance of instruments under controlled  
2858 conditions and to measure differences against certified references or other standards (e.g.  
2859 JOSIE). Data from these experiments can be used to detect biases that may be corrected  
2860 for and to determine calibration uncertainties.
  - 2861 3. Field inter-comparisons (dual or multi sonde launches on a single payload) allow multiple  
2862 in-situ sensors to be directly compared under the actual atmospheric conditions of the  
2863 required measurement, including the complex environmental conditions (temperature,  
2864 humidity, pressure, wind/flow rate, radiation, and chemical composition) that cannot be  
2865 fully reproduced in the laboratory. These complementary activities increase confidence  
2866

2867 that measurements are subject to neither unanticipated effects nor undiscovered  
2868 systematic uncertainties. Therefore field experiments are particularly useful for assuring  
2869 the quality of GRUAN data products.

2870 QC will be achieved through the application of the various measurement protocols defined in this  
2871 Document and in related measurement system documents (e.g. Lidar, Radiosonde technical  
2872 documents). To the extent possible, visual inspection of all data by science/instrument experts  
2873 will be required for ozonesondes to minimize anomalies that slip through automated routines.  
2874 The Lead Centre shall coordinate this effort, which shall be distributed across different GRUAN  
2875 sites and other interested parties as deemed appropriate including task teams and members of  
2876 WG-GRUAN. Vertically resolved uncertainty estimates, calculated by the GOASS for each site,  
2877 will be used as a metric to compare the site-to-site quality of the observations.

2878  
2879 Quality management is required at all points in the measurement process from network planning  
2880 and training, through installation and site operations to data transmission and archiving. This  
2881 quality management must include feedback and follow-up provisions across a range of  
2882 timescales from sonde conditioning to annual reviews. Because of the emphasis on the provision  
2883 of robust measurement uncertainties and the associated requirement for in-depth quality  
2884 management, the resources required within GRUAN to undertake quality management will likely  
2885 be a significant proportion of the cost of operating the network, and very likely more than the  
2886 few percent of overall operating costs typical of many observational networks. However, without  
2887 this expenditure, the quality of the data will be unknown, and their usefulness diminished.

2888  
2889 A key aspect of quality management within GRUAN will be fulfilling customer requirements.  
2890 To this end systems shall be developed to:

- 2891  
2892 1. Inform users of GRUAN products of changes in measurements systems at specific sites.  
2893 2. Provide an incident reporting system that can flag data anomalies to users.  
2894 3. Inform users of the availability of updates to previously accessed data products.  
2895 4. Provide “help desk” support to users of GRUAN data products.  
2896 5. Establishing close working relationships with instrument manufacturers will also be  
2897 central to quality assurance within GRUAN.  
2898

## 2899 **8.1 Assuring the quality of GRUAN Ozone sonde Programmes**

2900 The purpose of quality management is to ensure that GRUAN data meet the requirements in  
2901 terms of uncertainty, resolution, continuity, homogeneity, representativeness, timeliness, format  
2902 etc. for their intended use, at a minimum practicable cost. GRUAN recognizes that all  
2903 measurements are imperfect, but, if their quality is known and demonstrable, they can be used  
2904 appropriately. Minimizing cost without compromising quality is also an implied or explicit  
2905 requirement for measurements made within GRUAN.

2906  
2907 Five critical components are required to assure the long-term quality of GRUAN Ozone sonde  
2908 Programmes include:  
2909

- 2910 1. Maintaining consistent, up-to-date SOPs to minimize systematic errors and lend  
2911 confidence in the observed trends.  
2912 2. GRUAN-specific training of the representative and ozonesonde technicians of candidate  
2913 ozonesonde sites, the purpose of which is to ensure that the latest GRUAN-recommended  
2914 best practices for ozonesonde operations are observed.  
2915 3. The RSLaunchClient utility, the purpose of which is to upload, the raw measurement data  
2916 and metadata to the GRUAN central ozonesonde data processing facility.  
2917 4. The GOASS, the purpose of which is to analyses in a consistent manner the converted  
2918 raw ozonesonde data (CRD) through the RSLaunchClient, and to calculate the  
2919 ozonesonde SGDP and their uncertainties.  
2920 5. Maintaining documentation and statistics on flagged metadata (addressed in Section 3.7),  
2921 and missing raw data to be used as a diagnostic tool as part of the quality control  
2922 assessment and to ensure the continuity of individual GRUAN Ozonesonde Programmes.  
2923

2924 Routine testing of newly manufactured ozonesondes, changes in instrument design or solution  
2925 recipes will help to ensure confidence in observed trends in the future. Therefore, as part of the  
2926 quality assurance (QA) for ozonesondes that are in routine use, GRUAN shall follow protocols  
2927 established by the Forschungszentrum Jülich which houses the World Calibration Center for  
2928 Ozone Sondes (WCCOS) [<http://www.fz-juelich.de/iek/iek-8/EN/Expertise/Infrastructure/WCCOS/WCCOS.html?nn=865134>]. The simulation facility  
2929 enables control of pressure, temperature and ozone concentration and can simulate flight  
2930 conditions of ozone soundings up to an altitude of 35 km, whereby a UV photometer serves as a  
2931 reference [Smit et al., 1998]. The long term objective of WCCOS is to ensure three major QA-  
2932 tasks:  
2933

- 2934  
2935 1. QA-Procedures: Establishment and up-date of SOPs of different sonde types.  
2936 2. QA-Manufacturers: Performance check of ozonesondes from different manufacturers  
2937 3. QA-Operation: Evaluation of ozonesonde operating practice of difference sounding  
2938 laboratories

## 2939 8.2 Raw data validation

2940 Quality control at the raw data level is performed in two steps, first through uploads of the most  
2941 recently acquired raw data and associated metadata through the RSLaunchClient utility, then  
2942 through the threshold quality checks at the early processing stage of the GOASS (selection  
2943 criteria are addressed in Table 3.7.1 of Section 3.7). The suitability check of the raw data and  
2944 metadata to be accepted as part of the GOASS processed stream serves as a means to verify the  
2945 completeness of the information required by the RSLaunchClient.  
2946

## 2947 8.3 Ozonesonde data product validation

2948 Ozone profiles derived from GRUAN Ozonesonde Programmes will, in the first instance, be  
2949 validated against available redundant ozone profile measurements made at GRUAN sites (refer  
2950 to Section 4.1.2). Multiple measurements of ozone will be invaluable for identifying,  
2951 understanding and reducing systematic effects in ozonesonde measurements. One important  
2952 factor for GRUAN is that redundant measurements of the same (or related) variables should be

2953 reported in a consistent way. The cross-checking of redundant measurements for consistency  
2954 should be an essential part of the GRUAN quality assurance procedures. Since all data are to be  
2955 reported with uncertainties, a consistency check should, in principle, be a straight forward task.  
2956

2957 Satellite-based measurements of total column ozone (e.g. OMI, GOME-2) and profiles of ozone  
2958 in the lower stratosphere (e.g. Aura/MLS) are common reference measurements that can be used  
2959 to assess the quality of ozonesonde observations. GRUAN shall, where practical, schedule  
2960 ozonesonde launches in near real-time (i.e. within 2 hours of a satellite overpass) to fulfill the  
2961 requirement of providing a reference to satellite measurements.  
2962

2963  
2964  
2965

2966 In addition, GRUAN Ozonesonde Programmes are encouraged to participate in field campaigns  
2967 involving non-GRUAN instruments. All comparisons should be made between measurements  
2968 independent from each other. If two measurements are known to be dependent, the degree of this  
2969 dependence as well as its consequences must be specifically described and taken into account in  
2970 the product assessment. As stated in Section 10 of the GCOS-171, “Agreement of two  
2971 independent measurements, preferably based on different measurement principles, provides a  
2972 high degree of confidence that no significant systematic effect was disregarded and uncertainties  
2973 were not underestimated”.

#### 2974 **8.4 Performance monitoring system**

2975 Applying the principles described in Section 10 of the GCOS-171 to GRUAN Ozonesonde  
2976 Programmes, performance monitoring is a non-real-time activity in which the performance of an  
2977 individual GRUAN Ozonesonde Programme, or of an ensemble of GRUAN Ozonesonde  
2978 Programmes, is examined for trends and systematic deficiencies. Performance monitoring within  
2979 GRUAN Ozonesonde Programmes is primarily the responsibility of the Lead Centre and the  
2980 TTS.  
2981

2982 Certification and re-certification of GRUAN Ozonesonde Programmes is an essential component  
2983 of performance monitoring. Examples of quantitative performance indicators are:  
2984

- 2985 1. Ozonesonde SGDP downloads
- 2986 2. Number of candidate sites wishing to become a GRUAN Ozonesonde Programme.
- 2987 3. Number of GRUAN sites participating in JOSIE and inter-comparison field campaigns,  
2988 and conducting laboratory studies whose results appear in peer reviewed journals.
- 2989 4. The number of peer reviewed publications in which GRUAN ozonesonde data products  
2990 have been used.
- 2991 5. The number of GRUAN Ozonesonde Programmes funded through national or  
2992 international funding agencies.  
2993

2994 All above indicators serve to provide a year-to-year traceability of GRUAN ozonesonde  
2995 programmes' impact within the climate community.  
2996

3136 **TYPE**: TOTEX \_\_\_\_ Hwoyee \_\_\_\_ PAWAN \_\_\_\_ ( $\surd$  one)  
3137  
3138 **SURFACE PRESS**: \_\_\_\_\_ (hPa)    **SURFACE WIND SPEED**: \_\_\_\_\_ (m/s)  
3139 **SURFACE TEMP**: \_\_\_\_\_ (C)    **SURFACE WIND DIR**: \_\_\_\_\_ (deg)  
3140 **SURFACE RH**: \_\_\_\_\_ (%)  
3141 **Sky Conditions and General Remarks**:  
3142  
3143  
3144

3145 **Appendix A.2: RECOVERED OZONESONDE CHECKLIST**

3146 *Follows the NOAA/ESRL/GMD Check list*

3147

3148 DATE (YYYYMMDD): \_\_\_\_\_

3149 OPERATOR INITIALS: \_\_\_\_\_

3150

3151 Was this a GPS Sonde recovered on day of flight? \_\_\_\_ Yes/No

3152 If No, how many days between launch and recovery? \_\_\_\_ days

3153

3154 **HISTORY:**

3155 O<sub>3</sub> PUMP SERIAL #: \_\_\_\_\_

3156 FORMER FLIGHT #: \_\_\_\_\_

3157 DATE FLOWN (YYYYMMDD): \_\_\_\_\_

3158 DATE FOUND (YYYYMMDD): \_\_\_\_\_

3159 DATE RETURNED (YYYYMMDD): \_\_\_\_\_

3160

3161 **COMMENTS: OVERALL SONDE/PUMP CONDITION:** (looks new, dirt or coloring around  
3162 pump present, signs of corrosion anywhere, 0-ring condition, pump noisy?, etc.)

3163

3164

3165

3166

3167

3168

3169

3170

---

3171 **INITIAL RINSE/RECONDITIONING – SOON AFTER DELIVERY:**

3172

3173 Check that the cam that drives the piston is not turning off-center, loose or rubbing too close to  
3174 the metal frame. If it is too close or has come loose then the sonde will be noisy and run with a  
3175 high current. Sonde should not be flown in this case.

3176

3177 Rinse off outside of cells with warm tap water. \_\_\_\_ (√)

3178 Squirt De-ionized water (DIW) through running pump inlet (2 or 3 times for about 5 seconds).  
3179 \_\_\_\_ (√)

3180 Rinse cells and tubing with DIW. \_\_\_\_ (√)

3181 Fill cells about  $\frac{3}{4}$  full of DIW. \_\_\_\_ (√)

3182 Store sheet and ozonesonde until ready for the 3-7 day pre-condition. \_\_\_\_ (√)

3183 Date stored on shelf until ready for the 3-7 day pre-condition (YYYYMMDD):

3184 \_\_\_\_\_

3185

3186 **During normal pre-conditioning preparations**, an ozone calibrator, e.g. TEI, is strongly  
3187 recommended to test the performance of the refurbished sonde. Re-conditioned sondes should  
3188 not be flown if the sonde values are  $\pm 5\%$  of calibrated source.  
3189

3190 **PRE-CONDITIONING CALIBRATION PROCEDURES:**

3191  
3192 **DATE (YYYYMMDD):** \_\_\_\_\_

3193 Operator Initials: \_\_\_\_\_

3194  
3195 Calibration Instrument/Model: \_\_\_\_\_

3196 Calibration Serial Number: \_\_\_\_\_

3197

3198 1. Run 50 ppbv O<sub>3</sub> for 10 minutes: \_\_\_\_ (√)

3199 2. Record: CALIBRATOR: \_\_\_\_\_ ppbv OZONESONDE: \_\_\_\_\_ ppbv % Difference: \_\_\_\_

3200 **3. Run 100 ppbv O<sub>3</sub> for 10 minutes: \_\_\_\_ (√)**

3201 **4. Record: CALIBRATOR: \_\_\_\_\_ ppbv OZONESONDE: \_\_\_\_\_ ppbv % Difference:**

3202 \_\_\_\_\_

3203 5. Run 150 ppbv O<sub>3</sub> for 10 minutes: \_\_\_\_ (√)

3204 6. Record: CALIBRATOR: \_\_\_\_\_ ppbv OZONESONDE: \_\_\_\_\_ ppbv % Difference:

3205 \_\_\_\_\_

3206 7. Run 200 ppbv O<sub>3</sub> for 10 minutes: \_\_\_\_ (√)

3207 8. Record: CALIBRATOR: \_\_\_\_\_ ppbv OZONESONDE: \_\_\_\_\_ ppbv % Difference: \_\_\_\_

3208 9. Run 50 ppbv O<sub>3</sub> for 10 minutes: \_\_\_\_ (√)

3209 10. Record: CALIBRATOR: \_\_\_\_\_ ppbv OZONESONDE: \_\_\_\_\_ ppbv % Difference:

3210 \_\_\_\_\_

3211 **11. Run no ozone air for 10 minutes: \_\_\_\_ (√)**

3212 **12. Record: CALIBRATOR: \_\_\_\_\_ ppbv OZONESONDE: \_\_\_\_\_ ppbv % Difference:**

3213 \_\_\_\_\_

3214

3215 If the percentage differences for the 100 ppbv and ozone-free air exceeds  $\pm 5\%$  do **not** fly re-used  
3216 sonde.

3217

3218

3219 FINAL COMMENTS:
